1. Introduction

The purpose of this document is to establish a baseline standard of technical security controls for information systems for the Defense Security Service's (DSS) National Industrial Security Program and its participants. The protection of classified information maintained, hosted, or processed within computer systems necessitates the need for strong technical security controls to the maximum extent possible. These Baseline Standards currently contain the specific settings for securing the Microsoft Windows operating systems. ***This document will change shortly to include other Operating Systems.*** The configuration settings are based on documentation containing a comparison of different settings recommended by **Defense Information System Agency (DISA), National Institute of Standards and Technology (NIST), National Security Agency (NSA), Microsoft, and NISPOM** standards. This document will not provide the step by step recommended setting implementations, discuss some of the risks that are associated with a particular setting. A separate document will provide the step-by-step implementation for the baseline settings found in this document. In addition, an automated tool is developed that will facilitate the configurations outlined in this document.

The use of these Defense Security Service (DSS) Baseline Standards will strengthen system security controls and expedite DSS certification and accreditation reviews and on-site verifications.

2. General Assumptions

- Servers and Workstations are physically secured.
- Only system administrators are local administrators.
- Every administrator (each person) has a separate account, i.e. no shared administrator accounts.
- Installation and patching is done OFF the network, so server isn't exploited prior to patching.
- All drives are formatted NTFS.
- Email will not be read on the server by anyone.
- Remote access software will not be installed. Windows Terminal Services in application mode can be employed if remote console access is required by non-administrators.

- No account will be logged in at the console continuously. Most processes can be configured to run as a service. Processes which must be run from the console and not as a service require a locked console.

If these assumptions are not true, document the reason for the exceptions in order to facilitate Defense Security Service staff performing certification and accreditation.

3. System Basic

- Applications should not be installed on the system drive.
- User or application data should not be stored on the system drive.
- Only administrators should have access to the system drive or partitions.
- Replace Everyone ACLs with Authenticated Users, Domain Users, or a more restrictive group.
- Web browsing from a server is a security risk due to browser security issues. If browsing is required, server-based browsers should be vigilantly patched, and if possible restrictions on use should be employed.
- Any service which requires a service account which is a domain user should be documented as a known security issue. Should the server be compromised these accounts can easily be used to further compromise other domain systems. Pre-built code which will grab the password for service accounts (given a system level compromise) is easy to obtain on the internet.
- IPSec is strongly encouraged for enhanced security if all client operating systems are Windows 2000 or higher.
- Consider implementing SMB signing and secure channel encryption if all clients have an AD client.

This part of the document discusses those Group Policy settings that are applied at the Domain Level. The built-in Default Domain Controller policy includes default setting values for these policies, which are collectively referred to as Account policies.

The baseline standards and settings provide a high level of security for Windows XP Professional systems when used in conjunction with a sound and comprehensive local security policy and other relevant security controls.

4. Components Overview

This section presents an overview of the various security features offered by the Windows XP / 2003 Server operating system (OS). Many of the components have been inherited from Windows 2000, often with improvements and enhancements. Windows XP also includes several new security features.

4.1 Account Policies

There are three different types of Account policies: password policies, account lockout policies, and Kerberos authentication protocol policies. A single Microsoft Windows Server™ 2003 domain may have one of each of these policies. If these policies are set at any other level in Active Directory, only local accounts on member servers will be affected.

***Note:** For domain accounts, there can be only one Account policy per domain. The Account policy must be defined in the Default Domain Policy or in a new policy that is linked to the root of the domain and given precedence over the Default Domain Policy, which is enforced by the domain controllers that make up the domain. A domain controller always pulls the Account policy from the root of the domain, even if there is a different Account policy applied to the OU that contains the domain controller. The root of the domain is the top level container of the domain, not to be confused with the root domain in a forest; the root domain in a forest is the top level domain within that forest.*

The Account policy settings in Group Policy are all applied at the domain level. Default values are present in the built-in Default Domain Controller policy for password policies, account lockout policies, and Kerberos policies. When you configure these policies in the Active Directory® directory service, remember that Microsoft® Windows® only allows one domain Account policy—the Account policy that is applied to the root domain of the domain tree. The domain Account policy will become the default Account policy of any Windows computer that is a member of the domain.

The only exception to this rule is when another Account policy is defined for an organizational unit (OU). The Account policy settings for the OU will affect the Local Policies on any computers that are contained in the OU. For example, if an OU policy defines a maximum password age that differs from the domain-level Account policy, the OU policy will only be applied and enforced when users log on to the local computer. Only default local computer policies will apply to computers that are in a workgroup or in a domain where neither an OU Account policy nor a domain policy applies.

The settings for each of these policy types are discussed throughout this document.

4.2 Password Policy

In Windows and many other operating systems, the most common method to authenticate a user's identity is to use a secret pass phrase or password. A secure network environment requires all users to use strong passwords (ones that have at least ten characters and include a combination of letters, numbers, and symbols). These passwords help prevent the compromise of user accounts and administrative accounts by unauthorized people who use either manual methods or automated tools to guess weak passwords. Strong passwords that are changed regularly reduce the likelihood of a successful password attack. (More detailed information about strong passwords is provided in the "Passwords must meet complexity requirements" section later in this document.)

You can enforce the use of strong passwords through an appropriate password policy. Password policy settings control the complexity and lifetime of passwords. This section discusses each specific password policy account setting. You can configure the password policy settings in the following location within the Group Policy Object Editor:

**Computer Configuration\Windows Settings\Security Settings\
Account Policies\Password Policy**

If groups exist that require separate password policies, they should be segmented into another domain or forest based on any additional requirements.

Password Policy	Multitier Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p><i>Set the Password History Requirements</i></p> <p><i>Security Objective:</i> Set limit on how often passwords may be reused.</p> <p><i>Vulnerability:</i></p> <p>Password reuse is an important concern in any organization. Many users will want to use or reuse the same password for their account over a long period of time. The longer the same password is in use for a particular account, the greater the chance that an attacker will be able to determine the password through brute-force attacks. Also, any accounts that may have been compromised will remain exploitable for as long as the password is left unchanged. If password changes are required but password reuse is not prevented, or if users can continually reuse a small number of passwords, the effectiveness of a good password policy is greatly reduced. If you specify a low number for this policy setting, users will be able to use the same small number of passwords repeatedly. If you do not also configure the Minimum password age setting, users will be able to repeatedly change their passwords until they can reuse their original password.</p> <p><i>Procedure:</i></p> <ol style="list-style-type: none"> Double click on the Enforce password history policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the passwords remembered field (maximum is 24) to reflect the number of passwords the system will remember. A recommended setting is 24 passwords remembered. 	24	24	24

Password Policy	Multitier Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Set the Maximum Password Age</p> <p>Security Objective: Set the length of time users can keep their passwords before they have to change them.</p> <p>Vulnerability:</p> <p>Any password, even the most complex password, can be guessed (or "cracked") by an attacker with sufficient time and computer processing power. Some of the following policy settings can make it harder to crack passwords in a reasonable amount of time. The risk of a valid password being cracked can be reduced if users are frequently required to change their passwords, which can also mitigate the risk of unauthorized logon by someone who wrongfully acquired a password. You can configure the Maximum password age setting so that users are never required to change their passwords, but such a configuration would be a major security risk</p> <p>The possible values for the Maximum password age setting are:</p> <ul style="list-style-type: none"> • A user-specified number of days between 0 and 999 • Not Define <p>Procedure:</p> <ol style="list-style-type: none"> Double click on the Maximum password age policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the days field to the desired number. A recommended setting is 42 days. <p>Note: The ST requires that the administrator be able to set a password expiration time, but does not specify an expiration period. A maximum password age must be set if a minimum password age is used.</p>	90	90	90

Password Policy	Multuser Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Set the Minimum Password Age</p> <p>Security Objective: Set the length of time users must keep a password before they can change it.</p> <p>Vulnerability: It is ineffective to require users to change passwords regularly if they can cycle through passwords until they can reuse a favorite password. Use this policy setting with the Enforce password history setting to prevent the reuse of old passwords. For example, if you configure the Enforce password history setting to ensure that users cannot reuse any of their last 12 passwords, they could change their password 13 times in a few minutes and reuse the password they started with unless you configure the Minimum password age setting to a number that is greater than 0. You must configure this policy setting to a number that is greater than 0 for the Enforce password history setting to be effective.</p> <p>Procedure:</p> <ol style="list-style-type: none"> Double click on the Minimum password age policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the days field to the desired number. A recommended setting is 1 days. <p>Note: The ST requires that the administrator be able to set a minimum password age, but does not specify the length of time users must keep a password before they can change it. A minimum password age must be set if a maximum password age is used.</p>	1	1	1

Password Policy	Mutuser Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p><i>Minimum password length</i></p> <p>Security Objective: This policy setting determines the least number of characters that may make up a password for a user account. There are many different theories about how to determine the best password length for an organization, but perhaps "pass phrase" is a better term than "password." In Microsoft Windows 2000 and later versions, pass phrases can be quite long and they can include spaces, punctuation marks, and Unicode characters. Therefore, a phrase such as "I want to drink a \$5 beverage!" is a valid pass phrase. Such a phrase is considerably stronger than an 8 or 10 character string of random numbers and letters, but it is easier to remember.</p> <p>The possible values for the Minimum password length setting are:</p> <ul style="list-style-type: none"> • A user-specified number between 0 and 14 • Not Defined <p>Vulnerability:</p> <p>There are several types of password attacks that can be performed to obtain the password for a particular user account. These attacks include dictionary attacks (which attempt to use common words and phrases) and brute force attacks (which try every possible combination of characters). Also, attackers sometimes try to obtain the account database so they can use utilities to crack the accounts and passwords.</p> <p>Procedure:</p> <ol style="list-style-type: none"> Double click on the minimum password length policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select the number of characters required. 	12	12	12

Password Policy	Multiuser Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p><i>Set the Password Complexity Requirements</i></p> <p><i>Security Objective:</i> Requires the use of a complex (strong) password. This policy will impose a requirement for a combination of alphanumeric, special, and upper and lower case characters in a password.</p> <p><i>Vulnerability:</i></p> <p>Passwords that contain only alphanumeric characters are extremely easy to crack with several publicly available utilities. To prevent passwords from being cracked, they should contain a wider range of characters.</p> <p>The possible values for the Passwords must meet complexity requirements setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p><i>Procedure:</i></p> <p>c. Double click on the Passwords must meet complexity requirements policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window.</p> <p>d. Select the Enabled radio button.</p> <p><i>Note:</i> The ST does not specify password complexity requirements.</p>	Enabled	Enabled	Enabled
<p><i>Enable Reversible Encryption for Passwords</i></p> <p><i>Security Objective:</i> The Store password using reversible encryption for all users in the domain setting provides support for application protocols that require knowledge of the user's password for authentication purposes.</p> <p><i>Vulnerability:</i></p> <p>This policy setting determines whether Windows Server 2003 will store passwords in a weaker format that is much more susceptible to compromise.</p> <p>The possible values for the Store password using reversible encryption for all users in the domain setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p><i>Procedure:</i> Verify the default setting is “Disabled.”</p>	Disabled	Disabled	Disabled

4.3 Account Lockout Policy

More than a few unsuccessful password submissions during an attempt to log on to a computer might represent an attacker's attempts to determine an account password by trial and error. Windows Server 2003 with SP1 tracks logon attempts, and you can configure the operating system to disable the account for a preset period of time after a specified number of failed attempts. Account lockout policy settings control the threshold for this response and what action to take after the threshold is reached. You can configure the account lockout policy settings in the following location within the Group Policy Object Editor:

**Computer Configuration\Windows Settings\Security Settings\
Account Policies\Account Lockout Policy**

This setting will slow down a dictionary attack in which thousands of well-known passwords are tried. If the account is locked out after each invalid attempt to logon, the hacker must wait until the account is enabled again. If an account is locked out, the administrator can reset it using **Active Directory Users and Computers** for domain accounts or **Computer Management** for local accounts instead of waiting the allotted lockout duration. (NSA)

Account Lockout Policy	Multitier Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Account Lockout Duration</p> <p>Security Objective: This policy setting determines the number of minutes that a locked-out account remains locked out before it is automatically unlocked.</p> <p>Vulnerability:</p> <p>A denial of service (DoS) condition may be created if an attacker abuses the Account lockout threshold and repeatedly attempts to log on with a specific account. If you configure the Account lockout threshold setting, the account will be locked out after the specified number of failed attempts. If you configure the Account lockout duration setting to 0, then the account will remain locked out until an administrator unlocks it manually</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Double click on the Account policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the Account Duration field to set the duration of the lockout. <p>To specify that the account will remain locked until an administrator manually unlocks it, configure the value to 0. When the Account lockout duration setting is configured to a non-zero value, automated attempts to guess account passwords must wait out this interval before they resume attempts against a specific account.</p>	15	15	15
<p>Account lockout threshold</p> <p>Security Objective: This policy setting determines the number of failed logon attempts that causes a user account to become locked out.</p> <p>Vulnerability:</p> <p>Password attacks may use automated methods to try thousands or even millions of password combinations for any or all user accounts. The effectiveness of such attacks can be almost eliminated if you limit the number of failed logons that can be performed.</p> <p>However, it is important to note that a DoS attack could be performed on a domain that has an account lockout threshold configured. A malicious attacker could programmatically attempt a series of password attacks against all users in the organization. If the number of attempts is greater than the account lockout threshold, the attacker may be able to lock out every account.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Click on the Account Lockout policy object. Double click on the Account Lockout Threshold Setting dialog window. Configure the Account Lockout Threshold setting to 5. 	5	5	5

<p>Reset account lockout counter</p> <p>Security Objective: This policy setting determines the number of minutes that must elapse before the counter that tracks failed logon attempts and triggers account lockouts is reset to 0.</p> <p>Vulnerability: Users can accidentally lock themselves out of their accounts if they mistype their password multiple times. To reduce the chance of such accidental lockouts, the Reset account lockout counter after setting determines the number of minutes that must elapse before the counter that tracks failed logon attempts and triggers lockouts is reset to 0.. Procedure: Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Click on the Account Lockout policy object. Double click on the Reset account lockout counter Setting dialog window. Configure the Reset account lockout counter setting to 15. <p>Note: If an Account lockout threshold is defined, this reset time must be less than or equal to the Account lockout duration setting configuration.</p>	15	15	15
---	----	----	----

4.4 Kerberos Policy

In Windows Server 2003 with SP1, the Kerberos authentication protocol provides the default mechanism for domain authentication services and the authorization data that is necessary for a user to access a resource and perform a task on that resource. If the lifetime of Kerberos tickets is reduced, the risk of a legitimate user's credentials being stolen and successfully used by an attacker decreases. However, authorization overhead increases.

In most environments, the Kerberos policy settings should not need to be changed. These policy settings are applied at the domain level, and the default values are configured in the Default Domain Policy GPO in a default installation of a Windows 2000 or Windows Server 2003 Active Directory domain. You can configure the Kerberos policy settings in the following location within the Group Policy Object Editor:

**Computer Configuration\Windows Settings\Security Settings\
Account Policies\Kerberos Policy**

Kerberos is the default authentication method used in Windows 2000 Active Directory. Since Active Directory is necessary for Kerberos authentication, the Kerberos policy only has significance for the Windows 2000 domain Group Policy Object. Therefore, for the Windows XP workstation that this document addresses, the Kerberos policies will not be defined. (NSA)

Kerberos Policy Options	Multiuser Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Enforce user logon restrictions</p> <p>Security Objective: This policy setting determines whether the Key Distribution Center (KDC) validates every request for a session ticket against the user rights policy of the user account.</p> <p>The possible values for the Enforce user logon restrictions setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>If you disable this policy setting, users could receive session tickets for services that they no longer have the right to use because the right was removed after they logged on.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Double click on the Account policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the Kerberos Policy field to set the field options. Select Enforce user logon restrictions to enable the option. <p>Note: Validation of each request for a session ticket is optional, because the extra step takes time and may slow network access to services.</p>	Not Defined	Not Defined	Disable LM NTLM v.1 or Enabled if Kerberos is used

<p>Maximum lifetime for service ticket</p> <p>Security Objective: This policy setting determines the maximum amount of time (in minutes) that a granted session ticket can be used to access a particular service.</p> <p>The setting must be 10 minutes or greater, and less than or equal to the configuration of the Maximum lifetime for user ticket setting.</p> <p>If a client presents an expired session ticket when it requests a connection to a server, the server returns an error message and the client must request a new session ticket from the KDC. After a connection is authenticated, however, it does not matter if the session ticket remains valid. Session tickets are used only to authenticate new connections with servers. Operations are not interrupted if the session ticket that authenticated the connection expires during the connection.</p> <p>The possible values for the Maximum lifetime for service ticket setting are:</p> <ul style="list-style-type: none"> • A user-defined value in minutes between 10 and 99,999. If you configure this policy setting to 0, service tickets do not expire. • Not Defined. <p>Vulnerability:</p> <p>If you configure the value for the Maximum lifetime for service ticket setting too high, then users might be able to access network resources outside of their logon hours. Also, users whose accounts were disabled might have continued access to network services with valid service tickets that were issued before their accounts were disabled.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Double click on the Account policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the Kerberos Policy field to set the field options. Select Maximum lifetime for service ticket to enable the option. 	Not Defined	Not Defined	Not Defined
---	-------------	-------------	-------------

<p>Maximum lifetime for user ticket</p> <p>Security Objective: This policy setting determines the maximum amount of time (in hours) of a user's ticket-granting ticket (TGT). When a user's TGT expires, a new one must be requested or the existing one must be renewed.</p> <p>The possible values for the Maximum lifetime for user ticket setting are:</p> <ul style="list-style-type: none"> • A user-defined value in hours between 0 and 99,999. The default value is 10 hours. • Not Defined. <p>Vulnerability:</p> <p>If you configure the value for the Maximum lifetime for user ticket setting too high, then users might be able to access network resources outside of their logon hours. Also, users whose accounts were disabled might continue to have access to network services with valid service tickets that were issued before their accounts were disabled.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Double click on the Account policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the Kerberos Policy field to set the field options. Select Maximum lifetime for user ticket to enable the option. 	Not Defined	Not Defined	10 Hours
<p>Maximum lifetime for user ticket renew</p> <p>Security Objective: This policy setting determines the period of time (in days) during which a user's ticket-granting ticket (TGT) may be renewed.</p> <p>The possible values for the Maximum lifetime for user ticket renewal setting are:</p> <ul style="list-style-type: none"> • A user-defined value in minutes between 0 and 99,999 • Not Defined <p>Vulnerability:</p> <p>If the value for the Maximum lifetime for user ticket renewal setting is too high, then users may be able to renew very old user tickets.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Double click on the Account policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the Kerberos Policy field to set the field options. Select Maximum lifetime for user ticket renew to enable the option. 	Not Defined	Not Defined	10080 minutes or 7days

<p>Maximum tolerance for computer clock synchronization</p> <p>Security Objective: This policy setting determines the maximum time difference (in minutes) that the Kerberos protocol will allow between the time on the client computer's clock and the time on the Windows Server 2003–based domain controller that provides Kerberos authentication.</p> <p>The possible values for the Maximum tolerance for computer clock synchronization setting are:</p> <ul style="list-style-type: none"> • A user-defined value in minutes between 1 and 99,999 • Not Defined <p>Vulnerability:</p> <p>To prevent "replay attacks," the Kerberos authentication protocol uses time stamps as part of its protocol definition. For time stamps to work properly, the clocks of the client and the domain controller need to be synchronized as closely as possible. Because the clocks of two computers are often not synchronized, administrators can use this policy to establish the maximum elapsed time within which a Kerberos negotiation must complete; the elapsed time is computed from the timestamps. The value of this setting limits the maximum time difference that can be tolerated between the domain controller and the client computer.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Double click on the Account policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Change the number in the Kerberos Policy field to set the field options. Configure Maximum tolerance for computer clock synchronization setting to 5 minutes. 	Not Defined	Not Defined	5 Minutes
--	-------------	-------------	-----------

4.5 Audit Policy

An audit log records an entry whenever users perform certain specified actions. For example, the modification of a file or a policy can trigger an audit entry that shows the action that was performed, the associated user account, and the date and time of the action. You can audit both successful and failed attempts at actions.

The state of the operating system and applications on a computer is dynamic. For example, security levels may be temporarily changed to enable immediate resolution of an administration or network issue. However, such changes are often forgotten about and never undone. If security levels are not properly reset, a computer may no longer meet the requirements for enterprise security.

Regular security analyses enable administrators to track and determine that adequate security measures are in effect for each computer as part of an enterprise risk management program. Such analyses focus on highly specific information about all aspects of a computer that relate to security, which administrators can use to adjust the security levels. More importantly, this information can help detect any security flaws that may occur in the computer over time.

Security audits are extremely important for any enterprise network, because audit logs may provide the only indication that a security breach has occurred. If the breach is discovered some other way, proper audit settings will generate an audit log that contains important information about the breach.

Oftentimes, failure logs are much more informative than success logs because failures typically indicate errors. For example, successful logon to a computer by a user would typically be considered normal. However, if someone unsuccessfully tries to log on to a computer multiple times, it may indicate an attacker's attempt to break into the computer with someone else's account credentials. The event logs record events on the computer, and in Microsoft® Windows® operating systems, there are separate event logs for applications, security events, and system events. The Security log records audit events. The event log container of Group Policy is used to define attributes that relate to the Application, Security, and System event logs, such as maximum log size, access rights for each log, and retention settings and methods. You can configure the Audit policy settings in the following location within the Group Policy Object Editor:

**Computer Configuration\Windows Settings\Security Settings\
Local Policies\Audit Policy**

Auditing is critical to maintaining the security of the domain. On Windows XP systems, auditing is not enabled by default. Each Windows XP system includes auditing capabilities that collect information about individual system usage. The logs collect information on applications, system, and security events. Each event that is audited in an audit policy is written to the security event log, which can be viewed with the Event Viewer. (NSA)

Audit Policy	Multiuser Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Audit account logon events</p> <p>Security Objective: This policy setting determines whether to audit each instance of user logon or logoff on a different computer than the one that records the event and validates the account.</p> <p>Vulnerability: This policy setting specifies whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when an account logon attempt succeeds, which is useful information for accounting purposes and for post-incident forensics so that one can determine who successfully logged into which computer. Failure audits generate an audit entry when an account logon attempt fails, which is useful for intrusion detection. However, this policy setting also creates the potential for a denial of service (DoS) attack. When the Audit: Shut down system immediately if unable to log security audits setting is enabled, an attacker could generate millions of logon failures, fill the Security event log, and force the computer to shut down.</p> <p>Procedure: Under Local Security Policy or Default Domain Security Policy Local Policies</p> <ol style="list-style-type: none"> Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit account logon events field to set the audit event option. <p>Note: If you configure the Audit account logon events setting to Success on a domain controller, an entry is logged for each user who is validated against that domain controller, even though the user actually logs on to a workstation or server that is joined to the domain.</p>	Success, Failure	Success, Failure	Success, Failure

<p><i>Audit account management</i></p> <p><i>Security Objective:</i> This policy setting determines whether to audit each account management event on a computer. Examples of account management events include the following:</p> <ul style="list-style-type: none"> • A user account or group is created, changed, or deleted. • A user account is renamed, disabled, or enabled. • A password is set or changed. <p><i>Vulnerability</i></p> <p>Success audits generate an audit entry when any account management event succeeds, and the audit setting should be enabled them on all computers in the enclave. When an organization responds to security incidents, it is critical that they be able to track who created, changed, or deleted an account. Failure audits generate an audit entry when any account management event fails.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <ol style="list-style-type: none"> Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit account management field to set the audit event option. 	Success, Failure	Success, Failure	Success, Failure
<p><i>Audit Directory Services Access</i></p> <p><i>Security Objective:</i> This policy setting determines whether to audit user access of an Active Directory (AD) directory service object that has an associated system access control list (SACL). A SACL is list of users and groups for which actions on an object are to be audited on a Microsoft Windows-based network.</p> <p><i>Vulnerability:</i></p> <p>Success audits generate an audit entry when a user successfully accesses an Active Directory object that has a SACL that indicates that the user should be audited for the requested action. Failure audits generate an audit entry when a user unsuccessfully attempts to access an Active Directory object that has a SACL that requires auditing. (Both types of audit entries are created before the user is notified that the request succeeded or failed.)</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit directory service access field to set the audit event option. <p><i>Note:</i> You can configure a SACL on an Active Directory object through the Security tab in that object's Properties dialog box. This method is analogous to Audit object access, except that it applies only to Active Directory objects and not to file system and registry objects.</p>	Not Defined	Not Defined	For Servers that uses AD, Failure

<p><i>Audit Logon events</i></p> <p>Security Objective: This policy setting determines whether to audit each instance of user logon, logoff, or network connection to the computer that records the audit event.</p> <p>Vulnerability: Success audits generate an audit entry when a logon attempt succeeds, which is useful information for accounting purposes and for post-incident forensics so that you can determine who successfully logged on to which computer. Failure audits generate an audit entry when a logon attempt fails, which is useful for intrusion detection. However, this configuration also creates a potential DoS condition, because an attacker could generate millions of logon failures, fill the Security event log, and force the server to shut down.</p> <p>Procedure: Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit logon events field to set the audit event option. 	Success, Failure	Success, Failure	Success, Failure
---	------------------	------------------	------------------

<p>Audit Object Access</p> <p>Security Objective: This policy setting determines whether to audit the event of a user who accesses an object—for example, a file, folder, registry key, or printer—that has a SACL that specifies a requirement for auditing.</p> <p>Vulnerability</p> <p>Success audits generate an audit entry when a user successfully accesses an object that has a SACL. Failure audits generate an audit entry when a user unsuccessfully attempts to access an object that has a SACL (some failure events are to be expected during normal computer operations). For example, many applications (such as Microsoft Word) always attempt to open files with both read and write privileges. If the applications are unable to do so, they then try to open the files with read-only privileges. If you enable failure auditing and the appropriate SACL on the file, a failure event will be recorded when such an event occurs.</p> <p>In Microsoft Windows Server™ 2003 with Service Pack 1 (SP1), you can audit access to objects that are stored in the Internet Information server (IIS) metabase. To enable metabase object auditing, you must enable Audit object access on the target computer, and then set SACLs on the specific metabase objects whose access you want to audit.</p> <p>Configure the Audit object access policy setting and configure SACLs on objects, will generate a large volume of entries in the Security logs.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> c. Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. d. Select Local Security Setting Tab of Audit object access field to set the audit event option. <p>Note: You must perform a two-step process to enable the capability to audit an object, such as a file, folder, printer, or registry key, in Windows Server 2003. After you enable the audit object access policy, you must determine the objects whose access you want to monitor, and then modify their SACLs accordingly. For example, if you want to audit any attempts by users to open a particular file, you can configure a Success or Failure audit attribute directly on the file that you want to monitor for that particular event with Windows Explorer or Group Policy.</p>	Failure	Failure	Failure
---	---------	---------	---------

<p>Audit Policy Change</p> <p>Security Objective: This policy setting determines whether to audit every incidence of a change to user rights assignment policies, Windows Firewall policies, Audit policies, or trust policies.</p> <p>Vulnerability: This audit information is useful for accounting purposes and can help you determine who successfully modified policies in the domain or on individual computers. Failure audits generate an audit entry when a change to user rights assignment policies, Audit policies, or trust policies fails. If you enable the Audit policy change setting in Windows XP with SP2 and Windows Server 2003 with SP1, logging of configuration changes for the Windows Firewall component is also enabled.</p> <p>Procedure: Under Local Security Policy or Default Domain Security Policy Local Policies</p> <ol style="list-style-type: none"> Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit policy change field to set the audit event option. <p>Note: There exist problems with auditing successes of policy change. One such problem surfaces on the first system reboot after the “Audit: Shut down system immediately if unable to log security audits” (CrashOnAuditFail) security option is enabled. Upon reboot, the system will either blue screen or hang. Apparently, there is a problem writing a policy change event to the audit log, and thus, the system crashes. Subsequent reboots will be successful, but only an administrator can log on as designed. The administrator must then reset the CrashOnAuditFail registry key from 2 back to 0 or 1 in order for other users to access the system. This behavior does not exist if successful policy change audit is not enabled. (NSA)</p>	Success, Failure	Success, Failure	Success, Failure
---	------------------	------------------	------------------

<p>Audit Privilege Use</p> <p>Security Objective: This policy setting determines whether to audit each instance of a user who exercises a user right.</p> <p>Vulnerability:</p> <p>If you configure the Audit privilege use setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when the exercise of a user right succeeds. Failure audits generate an audit entry when the exercise of a user right fails. If you enable this policy setting, the volume of events that is generated can be very large and the events may be difficult to sort through. You should only enable this setting if you have a plan for how you will use the information that is generated.</p> <p>Audit events are not generated for use of the following user rights, even if success audits or failure audits are specified for this policy setting:</p> <ul style="list-style-type: none"> • Bypass traverse checking • Debug programs • Create a token object • Replace process level token • Generate security audits • Backup files and directories <p>Restore files and directories</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit privilege use field to set the audit event option. <p>Note: The Audit use of all user rights including Backup and Restore setting under Security Options will audit user rights excluded here. However, it will fill up the security event log very quickly and so is not recommended. (NSA)</p>	Success, Failure	Success, Failure	Success, Failure
---	------------------	------------------	------------------

<p>Audit Process Tracking</p> <p>Security Objective: This policy setting determines whether to audit detailed tracking information for events such as program activation, process exit, handle duplication, and indirect object access.</p> <p>Vulnerability:</p> <p>Success audits generate an audit entry when the process being tracked succeeds. Failure audits generate an audit entry when the process being tracked fails.</p> <p>If you enable Audit process tracking in Windows XP with SP2 and Windows Server 2003 with SP1, Windows will also log information about the operating mode and status of the Windows Firewall component.</p> <p>When enabled, the Audit process tracking setting generates a large number of events. This policy setting is typically configured to No Auditing. However, the information that this policy setting generates can be very beneficial during an incident response because it provides a detailed log of the processes that were started and when they were launched.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit process tracking field to set the audit event option. <p>NOTE: Enabling this setting will generate many events. Use only when absolutely necessary. (NIST)</p>	No Auditing	No Auditing	No Auditing
<p>Audit System Events</p> <p>Security Objective: This policy setting determines whether to audit when a user restarts or shuts down their computer, or when an event occurs that affects either computer security or the Security log.</p> <p>Vulnerability:</p> <p>If you configure the Audit system events setting, you can specify whether to audit successes, audit failures, or not audit the event type at all. Success audits generate an audit entry when an event executes successfully. Failure audits generate an audit entry when an event is unsuccessful. Because few additional events are recorded if both failure and success audits are enabled for system events, and because all such events are very significant, you should configure this policy setting to Enabled on all computers in your organization.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Audit policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit system events field to set the audit event option. <p>Note:</p> <p>Tracks events that affect the entire system or the Audit log. Records events such as restart or shutdown. (NSA)</p>	Success, Failure	Success, Failure	Success, Failure

More Information

The following links provide additional information about topics that relate to Audit policies for computers that run Windows XP with SP2 or Windows Server 2003 with SP1:

- For more Audit policy information, see the "[Auditing Policy](#)" section in the Windows Server 2003 TechCenter documentation on Microsoft TechNet at www.microsoft.com/technet/prodtechnol/windowsserver2003/library/ServerHelp/6847e72b-9c47-42ab-b3e3-691addac9f33.msp.
- The article "[HOW TO: Use Group Policy to Audit Registry Keys in Windows Server 2003](#)" at <http://support.microsoft.com/default.aspx?kbid=324739> describes how to audit access to registry keys by adding SACLS to those keys.
- The articles "[Windows 2000 Security Event Descriptions \(Part 1 of 2\)](#)" at <http://support.microsoft.com/kb/299475/> and "[Windows 2000 Security Event Descriptions \(Part 2 of 2\)](#)" at <http://support.microsoft.com/kb/301677/> describe the security events logged by Windows 2000 Server. They also apply to Windows Server 2003 and Windows XP.

4.6 User Rights

User rights allow users to perform tasks on a computer or a domain. User rights include *logon rights* and *privileges*. Logon rights control who is authorized to log on to a computer and how they can log on. Privileges control access to computer and domain resources, and can override permissions that have been set on specific objects. (Microsoft)

You can configure the user rights assignment settings in the following location within the Group Policy Object Editor:

**Computer Configuration\Windows Settings\Security Settings\
Local Policies\User Rights Assignment**

User Rights Assignments determine what actions users and groups are allowed to perform. Explicitly-granted user rights supplement implicit abilities of the user or group. Advanced user rights are assigned to Administrators or other trusted groups, who are allowed to run administrative utilities, install service packs, create printers, and install device drivers. (NSA)

User Rights Assignment	Multiuser Stand Alone	P2P LAN	Client/Server AD
<p><i>Access this computer from the network</i></p> <p><i>Security Objective:</i> This policy setting determines whether users can connect to the computer from the network. This capability is required by a number of network protocols, including Server Message Block (SMB)-based protocols, NetBIOS, Common Internet File System (CIFS), and Component Object Model Plus (COM+). The possible values for the Access this computer from the network setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p><i>Vulnerability:</i></p> <p>Users who can connect from their computer to the network can access resources on target computers for which they have permission. For example, the Access this computer from the network user right is required for users to connect to shared printers and folders. If this user right is assigned to the Everyone group and some shared folders have both share and NTFS file system (NTFS) permissions configured so that the same group has read access, then anyone in the group will be able to view files in those shared folders. However, this situation is unlikely for new installations of Microsoft Windows Server™ 2003 with Service Pack 1 (SP1), because the default share and NTFS permissions in Windows Server 2003 do not include the Everyone group. This vulnerability may have a higher level of risk for computers that you upgrade from Windows NT® 4.0 or Windows 2000, because the default permissions for these operating systems are not as restrictive as the default permissions in Windows Server 2003.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of the Access this computer from the network Properties Sheet. Select the user group and click to add or remove users or group. <p>Note: Networked systems may require services, thus the group Everyone may be required.</p>	Administrators, Users	Administrators, Users	Administrators, Users

<p><i>Act as part of the operating system</i></p> <p><i>Security Objective:</i> This policy setting determines whether a process can assume the identity of any user and thereby gain access to the resources that the user is authorized to access.</p> <p>The possible values for the Act as part of the operating system setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p><i>Vulnerability:</i></p> <p>The Act as part of the operating system user right is extremely powerful. Anyone with this user right can take complete control of the computer and erase evidence of their activities.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Act as part of the operating system Properties Sheet. Remove Local System from the list. 	None	None	None
---	------	------	------

<p>Add workstations to domain</p> <p>Security Objective: This policy setting determines whether a user can add a computer to a specific domain. For it to take effect, it must be assigned so that it applies to at least one domain controller.</p> <p>The possible values for the Add workstations to domain setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>The Add workstations to domain user right presents a moderate vulnerability. Users with this right could add a computer to the domain that is configured in a way that violates organizational security policies. For example, if your organization does not want its users to have administrative privileges on their computers, a user could install Windows on their computer and then add the computer to the domain. They would know the password for the local administrator account, and they could log on with that account and then add their domain account to the local Administrators group.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Add workstations to domain Properties Remove Authenticated Users from the list. For Domain Controller, adding systems should be performed by administrators only. 	None	None	Domain Administrators Only
<p>Adjust memory quotas for a process</p> <p>Security Objective: This policy setting determines whether users can adjust the maximum amount of memory that is available to a process.</p> <p>The possible values for the Adjust memory quotas for a process setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>A user with the Adjust memory quotas for a process privilege can reduce the amount of memory that is available to any process, which could cause business-critical network applications to become slow or to fail.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Adjust memory quotas for a process Properties. Users should not be able to perform this task 	Local Service, Administrators	Network Services, Local Service, Administrators	Network Services, Local Service, Administrators

<p>log on locally</p> <p>Security Objective: This policy setting determines whether a user can start an interactive session on the computer. Users who do not have this right are still able to start a remote interactive session on the computer if they have the Allow logon through Terminal Services right.</p> <p>The possible values for the log on locally setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>Any account with the Allow log on locally user right can log on at the console of the computer. If you do not restrict this user right to legitimate users who need to be able to log on to the console of the computer, unauthorized users could download and execute malicious code to elevate their privileges.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Allow log on locally Properties. Click on Add User or Groups to add user-defined list of accounts. Use Remove to remove accounts. <p>Note: If anonymous service is required to logon, then use expressive policy to add the services or users or groups to the list.</p>	Administrators, Authenticated Users	Administrators, Authenticated Users	Administrators, Authenticated Users
<p>Allow log on through Terminal Services</p> <p>Security Objective: This policy setting determines whether users can log on to the computer through a Remote Desktop connection.</p> <p>The possible values for the Allow log on through Terminal Services setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>Any account with the Allow log on through Terminal Services user right can log on to the remote console of the computer. If you do not restrict this user right to legitimate users who need to log on to the console of the computer, unauthorized users could download and execute malicious code to elevate their privileges.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Allow log on through Terminal Services Properties. Remove Remote Desktop User and Administrators. Add Administrators if required. 	None	None	None(Administrators if required)

<p>Backup files and Directories</p> <p>Security Objective: This policy setting determines whether users can circumvent file and directory permissions to back up the computer. This user right is effective only when an application attempts access through the NTFS backup application programming interface (API) through a backup utility such as NTBACKUP.EXE. Otherwise, standard file and directory permissions apply.</p> <p>The possible values for the Back up files and directories setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>Users who are able to back up data from a computer could take the backup media to a non-domain computer on which they have administrative privileges and restore the data. They could take ownership of the files and view any unencrypted data that is contained within the backup set.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Back up files and directories Properties. Click Add or Remove to modify user-defined list of accounts. Remove Backup operator if not needed. <p>Note: If the network makes use of the Backup Operators or similar group, also assign this right to that group. Keep in mind, however, that users who have this right have the ability to bypass ACLs. Unless FullPrivilegeAuditing is turned on, such access is not logged.</p>	Administrators	Administrators	Administrators
---	----------------	----------------	----------------

<p><i>Bypass traverse checking</i></p> <p><i>Security Objective:</i> This policy setting determines whether users can pass through folders without being checked for the special access permission “Traverse Folder” when they navigate an object path in the NTFS file system or in the registry.</p> <p>The possible values for the Bypass traverse checking setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p><i>Vulnerability:</i></p> <p>The default configuration for the Bypass traverse checking setting is to allow anyone to bypass traverse checking, and experienced Windows system administrators configure file system access control list (ACLs) accordingly. The only scenario in which the default configuration could lead to a mishap would be if the administrator who configures permissions does not understand how this policy setting works. For example, they might expect that users who are unable to access a folder will be unable to access the contents of any child folders. Such a situation is unlikely, and therefore this vulnerability presents little risk.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Bypass traverse checking Properties. Click Add or Remove to modify user-defined list of accounts. 	Administrators, Users	Administrators, Users	Administrators, Users
---	-----------------------	-----------------------	-----------------------

<p><i>Change the system time</i></p> <p><i>Security Objective:</i> This policy setting determines whether users can adjust the time on the computer's internal clock. It is not required to change the time zone or other display characteristics of the system time.</p> <p>The possible values for the Change the system time setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p><i>Vulnerability:</i></p> <p>Users who can change the time on a computer could cause several problems. For example, time stamps on event log entries could be made inaccurate, time stamps on files and folders that are created or modified could be incorrect, and computers that belong to a domain may not be able to authenticate themselves or users who try to log on to the domain from them. Also, because the Kerberos authentication protocol requires that the requestor and authenticator have their clocks synchronized within an administrator-defined skew period, an attacker who changes a computer's time may cause that computer to be unable to obtain or grant Kerberos tickets.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Change the system time Properties. Click Add or Remove to modify user-defined list of accounts. 	Administrators	Administrators	Administrators
<p><i>Create a page file</i></p> <p><i>Security Objective:</i> This policy setting determines whether users can create and change the size of a page file. Specifically, it determines whether they can specify a page file size for a particular drive in the Performance Options box that is located on the Advanced tab of the System Properties dialog box.</p> <p>The possible values for the Create a page file setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p><i>Vulnerability:</i></p> <p>Users who can change the page file size could make it extremely small or move the file to a highly fragmented storage volume, which could cause reduced computer performance.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Create a page file Properties. Click Add or Remove to modify user-defined list of accounts. 	Administrators	Administrators	Administrators

<p>Create a token object</p> <p>Security Objective: This policy setting determines whether a process can create a token, which it can then use to gain access to any local resources when the process uses NtCreateToken() or other token-creation APIs.</p> <p>The possible values for the Create a token object setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>The operating system examines a user's access token to determine the level of the user's privileges. Access tokens are built when users log on to the local computer or connect to a remote computer over a network. When you revoke a privilege, the change is immediately recorded, but the change is not reflected in the user's access token until the next time the user logs on or connects. A user with the ability to create or modify tokens can change the level of access for any currently logged on account. They could escalate their own privileges or create a DoS condition</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Create a token object Properties. Click Add or Remove to modify user-defined list of accounts. 	None	None	None
<p>Create global objects</p> <p>Security Objective: This policy setting determines whether users can create global objects that are available to all sessions. Users can still create objects that are specific to their own session if they do not have this user right.</p> <p>The possible values for the Create global objects setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>Users who can create global objects could affect processes that run under other users' sessions. This capability could lead to a variety of problems, such as application failure or data corruption.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Create global objects Properties. Click Add or Remove to modify user-defined list of accounts. Select INTERACTIVE, and SERVICE account click remove. Remove Administrators if terminal services are not used. 	None	None	None

<p>Create permanent shared objects</p> <p>Security Objective: This policy setting determines whether users can create directory objects in the object manager. Users who have this capability can create permanent shared objects, including devices, semaphores, and mutexes. This user right is useful to kernel-mode components that extend the object namespace, and they have this user right inherently. Therefore, it is typically not necessary to specifically assign this user right to any users.</p> <p>The possible values for the Create permanent shared objects setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>Users who have the Create permanent shared objects user right could create new shared objects and expose sensitive data to the network</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Create permanent shared objects Properties. Click Add or Remove to modify user-defined list of accounts. 	None	None	None
--	------	------	------

<p>Debug programs</p> <p>Security Objective: This policy setting determines whether users can open or attach to any process, even those that they do not own. This user right provides access to sensitive and critical operating system components.</p> <p>The possible values for the Debug programs setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p>Vulnerability:</p> <p>The Debug programs user right can be exploited to capture sensitive computer information from system memory, or to access and modify kernel or application structures. Some attack tools exploit this user right to extract hashed passwords and other private security information, or to effect rootkit code insertions. By default, the Debug programs user right is assigned only to administrators, which helps to mitigate the risk from this vulnerability.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Debug programs Properties. Click Add or Remove to modify user-defined list of accounts. <p>Note:</p> <p>Software developers working on the system may need this right to debug programs running as other users. Assign the right to developer users/groups only when necessary.</p> <p>Several Microsoft patches released around October 2003 required Administrators to have the Debug user right to install. This has since been changed and Administrators no longer require this right.</p> <p>(NSA)</p>	None	None	None
---	------	------	------

<p><i>Deny access to this computer from the network</i></p> <p>Security Objective: This policy setting determines whether users have the ability to connect to the computer from the network.</p> <p>The possible values for the Deny access to this computer from the network setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined. <p>Vulnerability:</p> <p>Users who can log on to the computer over the network can enumerate lists of account names, group names, and shared resources. Users with permission to access shared folders and files can connect over the network and possibly view or modify data. You can explicitly deny this user right to high-risk accounts (such as the local Guest account and other accounts that have no business need to access the computer over the network) to provide an additional layer of protection.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the User Rights Assignment policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Deny access to this computer from the networks Properties. Click Add for additional accounts to deny access. <p>Note:</p> <p>By default, the Guest and SUPPORT_388945a0 users are denied this right. <p><i>Impersonate a client after authentication</i></p> <p><i>Security Objective:</i> The Impersonate a client after authentication user right allows programs that run on behalf of a user to impersonate that user (or another specified account) so that they can act on behalf of the user. If this user right is required for this kind of impersonation, an unauthorized user will not be able to convince a client to connect—for example, by remote procedure call (RPC) or named pipes—to a service that they have created to impersonate that client, which could elevate the unauthorized user's permissions to administrative or system levels.</p> <p>Services that are started by the Service Control Manager have the built-in Service group added by default to their access tokens. COM servers that are started by the COM infrastructure and configured to run under a specific account also have the Service group added to their access tokens. As a result, these processes are assigned this user right when they are started.</p> <p>Also, a user can impersonate an access token if any of the following conditions exist:</p> <ul style="list-style-type: none"> • The access token that is being impersonated is for this user. • The user, in this logon session, logged on to the network with explicit credentials to create the access token. • The requested level is less than Impersonate, such as Anonymous or Identify. <p>Because of these factors, users do not usually need to have this user right assigned. The possible values for the Impersonate a client after authentication setting are:</p> <ul style="list-style-type: none"> • A user-defined list of accounts • Not Defined <p><i>Vulnerability:</i></p> <p>An attacker with the Impersonate a client after authentication user right could create a service, trick a client to make them connect to the service, and then impersonate that client to elevate the attacker's level of access to that of the client.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> a. More Information

The following links provide additional information about user rights assignment in Windows Server 2003 and Windows XP.

- Extensive information about assigning user rights with the SCE is available in the "[User Rights Assignment](#)" section of the Security Configuration Editor online help for Windows Server 2003 at www.microsoft.com/technet/prodtechnol/windowsserver2003/library/serverhelp/71b2772f-e3c0-4134-b7f0-54c244ee9aef.mspx.
- Detailed information about local user rights assignments on Windows XP computers is available in the help topic "[To assign user rights for your local computer](#)" at www.microsoft.com/resources/documentation/windows/xp/all/proddocs/en-us/lpe_assign_user_right.mspx.
- For more information about user rights assignments in Windows XP, see the "[User Rights Assignment](#)" section of the online Windows XP Professional documentation at www.microsoft.com/resources/documentation/windows/xp/all/proddocs/en-us/uratopnode.mspx.
- For more information about how to customize the Security Configuration Editor user interface, see the Microsoft Knowledge Base article "[How to Add Custom Registry Settings to Security Configuration Editor](#)" at <http://support.microsoft.com/?scid=214752>.
- For more information about how to create custom administrative template files in Windows, see the Microsoft Knowledge Base article "[How to: Create Custom Administrative Templates in Windows 2000](#)" at <http://support.microsoft.com/?scid=323639>.

4.7 Security Options

The Security Options section of Group Policy enables or disables computer security settings for digital data signatures, Administrator and Guest account names, access to floppy disk and CD-ROM drives, driver installation behavior, and logon prompts.

You can configure the security options settings in the following location within the Group Policy Object Editor:

**Computer Configuration\Windows Settings\Security Settings\
Local Policies\Security Options**

Security Options	Multituser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Accounts: Administrator account status</p> <p>Security Objective: This policy setting enables or disables the Administrator account for normal operational conditions. If you start a computer in safe mode, the Administrator account is always enabled, regardless of how you configure this policy setting.</p> <p>The possible values for the Accounts: Administrator account status setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>In some organizations, it can be a daunting management challenge to maintain a regular schedule for periodic password changes for local accounts. Therefore, you may want to disable the built-in Administrator account instead of relying on regular password changes to protect it from attack. Another reason to disable this built-in account is that it cannot be locked out no matter how many failed logons it accrues, which makes it a prime target for brute force attacks that attempt to guess passwords. Also, this account has a well-known security identifier (SID) and there are third-party tools that allow authentication by using the SID rather than the account name. This capability means that even if you rename the Administrator account, an attacker could launch a brute force attack by using the SID to log on.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Accounts: Administrator account status policy to set the radio options to Enable. <p>NOTE:</p> <p>Most security options are set via a registry key. The associated registry keys are listed for each item. Those options not containing a registry key are instead secured at the API level.</p>	Enabled	Enabled	Enabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Accounts: Guest account status</p> <p>Security Objective: This policy setting determines whether the Guest account is enabled or disabled. The possible values for the Accounts: Guest account status setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>The default Guest account allows unauthenticated network users to log on as Guest with no password. These unauthorized users could access any resources that are accessible to the Guest account over the network. This capability means that any network shares with permissions that allow access to the Guest account, the Guests group, or the Everyone group will be accessible over the network, which could lead to the exposure or corruption of data.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Accounts: Guest account status policy to set the radio options to Disable. <p>NOTE:</p> <p>If the Guest account is disabled and the security option, “Network access: Sharing and security model for local accounts” is set to “Guest Only,” network logons, such as those performed by the SMB Service, will fail.(NSA)</p>	Disabled	Disabled	Disabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Accounts: Limit local account use of blank passwords to console logon only</p> <p>Security Objective: This policy setting determines whether remote interactive logons by network services such as Terminal Services, Telnet, and File Transfer Protocol (FTP) are allowed for local accounts that have blank passwords. If you enable this policy setting, a local account must have a non-blank password to perform an interactive or network logon from a remote client.</p> <p>The possible values for the Accounts: Limit local account use of blank passwords to console logon only setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Note: This policy setting does not affect interactive logons that are performed physically at the console or logons that use domain accounts.</p> <p>Caution: It is possible for third-party applications that use remote interactive logons to bypass this policy setting.</p> <p>Vulnerability:</p> <p>Blank passwords are a serious threat to computer security and should be forbidden through both organizational policy and suitable technical measures. In fact, the default settings for Windows Server 2003 Active Directory® directory service domains require complex passwords of at least seven characters. However, if a user with the ability to create new accounts bypasses your domain-based password policies, they could create accounts with blank passwords. For example, a user could build a stand-alone computer, create one or more accounts with blank passwords, and then join the computer to the domain. The local accounts with blank passwords would still function. Anyone who knows the name of one of these unprotected accounts could then use it to log on.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of blank passwords to console logon only field to set the radio options to Enable. <p>Note:</p> <p>This setting only affects local accounts. It does not affect domain accounts.</p> <p>HKLM\System\CurrentControlSet\Control\Lsa\LimitBlankPasswordUse = 1(NSA)</p>	Enabled	Enabled	Enabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Accounts: Rename administrator account</p> <p>Security Objective: This policy setting determines whether a different account name is associated with the SID for the Administrator account.</p> <p>The possible values for the Accounts: Rename administrator account setting are:</p> <ul style="list-style-type: none"> • User-defined text • Not Defined <p>Vulnerability:</p> <p>The Administrator account exists on all computers that run the Windows 2000, Windows Server 2003, or Windows XP Professional operating systems. If you rename this account, it is slightly more difficult for unauthorized persons to guess this privileged user name and password combination.</p> <p>The built-in Administrator account cannot be locked out, regardless of how many times an attacker might use a bad password. This capability makes the Administrator account a popular target for brute force attacks that attempt to guess passwords. The value of this countermeasure is lessened because this account has a well-known SID, and there are third-party tools that allow authentication by using the SID rather than the account name. Therefore, even if you rename the Administrator account, an attacker could launch a brute force attack by using the SID to log on.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Accounts: Rename administrator account policy to set the options by entering the new account name in the text field. <p>Note:</p> <p>If anonymous accounts are not restricted from enumerating users on the system, renaming the administrator account will have limited benefit. However, if the anonymous user is prohibited from gathering account information, renaming the administrator account is provides much more benefit. See security options affecting anonymous privileges in the Network Access section of this table. (NSA)</p>	Rename to contractor's standard	Rename to contractor's standard	Rename to contractor's standard

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Accounts: Rename Guest account</p> <p>Security Objective: The Accounts: Rename guest account setting determines whether a different account name is associated with the SID for the Guest account.</p> <p>The possible values for this Group Policy setting are:</p> <ul style="list-style-type: none"> • User-defined text • Not Defined <p>Vulnerability:</p> <p>The Guest account exists on all computers that run the Windows 2000, Windows Server 2003, or Windows XP Professional operating systems. If you rename this account. It is slightly more difficult for unauthorized persons to guess this privileged user name and password combination.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Accounts: Rename Guest account policy to set the options by entering the new account name in the text field. 	Rename to contractor's standard	Rename to contractor's standard	Rename to contractor's standard

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p><i>Audit: Audit the access of global system objects</i></p> <p><i>Security Objective:</i> If you enable this policy setting, a default system access control list (SACL) will be applied when the computer creates system objects such as mutexes, events, semaphores, and MS-DOS® devices. If you also enable the Audit object access audit setting as described in this document, access to these system objects is audited.</p> <p>Global system objects, also known as “base system objects” or “base named objects,” are ephemeral kernel objects that have had names assigned to them by the application or system component that created them. These objects are most commonly used to synchronize multiple applications or multiple parts of a complex application. Because they have names, these objects are global in scope, and therefore visible to all processes on the computer. These objects all have a security descriptor but typically have a NULL SACL. If you enable this policy setting at startup time, the kernel will assign a SACL to these objects when they are created.</p> <p>The possible values for the Audit: Audit the access of global system objects setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of system objects field policy to set the radio options of Disable. <p><i>Note:</i></p> <p>Enabling this option will result in large numbers of events being written to the security logs. Coupled with the fact that global system audit events are difficult to decipher, it is recommended that this option be enabled only when deemed absolutely necessary. To audit access to system objects, the “Audit object access” audit policy must be enabled.</p>	Disabled	Disabled	Disabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p><i>Audit: Audit the use of Backup and Restore privilege</i></p> <p><i>Security Objective:</i> This policy setting determines whether to audit the use of all user privileges, including Backup and Restore, when the Audit privilege use setting is in effect. If you enable both policy settings, an audit event is generated for every file that is backed up or restored.</p> <p>If you enable this policy setting in conjunction with the Audit privilege use setting, any exercise of user rights in the Security log is recorded. If you disable this policy setting, actions by users of Backup or Restore privileges are not audited, even if Audit privilege use is enabled.</p> <p>The possible values for the Audit: Audit the use of Backup and Restore privilege setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p><i>Vulnerability:</i></p> <p>If you enable this option when the Audit privilege use setting is also enabled, an audit event is generated for every file that is backed up or restored. This information could help you to identify an account that was used to accidentally or maliciously restore data in an unauthorized manner.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Audit: Audit the use of Backup and Restore privilege policy to set to Disabled. <p><i>Note:</i></p> <p>To audit user rights, the “Audit privilege use” audit policy must be enabled. HKLM\System\CurrentControlSet\Control\Lsa\FullPrivilegeAuditing</p>	Disabled	Disabled	Disabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p><i>Audit: Shut down system immediately if unable to log security audits</i></p> <p>Security Objective: This policy setting determines whether the computer shuts down if it is unable to log security events. The Trusted Computer System Evaluation Criteria (TCSEC)-C2 and Common Criteria certifications require that the computer be able to prevent the occurrence of auditable events if the audit system is unable to log them. The way that Microsoft chose to meet this requirement is to halt the computer and display a stop message in the case of a failure of the audit system. If you enable this policy setting, the computer stops if a security audit cannot be logged for any reason. Typically, an event fails to be logged when the Security event log is full and its specified retention method is either Do Not Overwrite Events or Overwrite Events by Days.</p> <p>When this policy setting is enabled, the following Stop message displays if the security log is full and an existing entry cannot be overwritten:</p> <p>STOP: C0000244 {Audit Failed}</p> <p>An attempt to generate a security audit failed.</p> <p>To recover, an administrator must log on, archive the log (optional), clear the log, and disable this option to allow the computer to be restarted. At that point, it may be necessary to manually clear the Security event log before you can configure this policy setting to Enabled.</p> <p>The possible values for the Audit: Shut down system immediately if unable to log security audits setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>If the computer is unable to record events to the Security log, then critical evidence or important troubleshooting information may not be available for review after a security incident. Also, an attacker could potentially generate a large volume of Security event log messages to purposely force a computer shutdown.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting tab of Audit: Shut down system immediately if unable to log security audits policy to set the radio option to Enable. <p>Note:</p> <p>It is generally recommended that this setting be enabled; however due to a problem that exists with auditing successful policy changes we are recommending that this setting be disabled until the issue is resolved. The problem surfaces on the first system reboot after the “Audit: Shut down system immediately if unable to log security audits” security option is enabled. Upon reboot, the system will either blue screen or hang. Apparently, there is a problem writing a policy change event to the audit log, and thus, the system crashes. Subsequent reboots will be successful. When the machine reboots, only an administrator can log on. The administrator must then reset the CrashOnAuditFail registry key from 2 back to 0 or 1 in order for other users to access the system. This behavior does not exist if successful policy change audit is not enabled. (NSA)</p> <p>HKLM\System\CurrentControlSet\Control\Lsa\CrashOnAuditFail=0</p>	Enabled	Enabled	Enabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>DCOM: Machine Access Restrictions in Security Descriptor Definition Language (SDDL)</p> <p>Security Objective: This policy setting allows administrators to define additional computer-wide access controls that govern access to all Distributed Component Object Model (DCOM)–based applications on a computer. These controls restrict call, activation, or launch requests on the computer. The simplest way to think about these access controls is as an additional access check call that is done against a computer-wide access control list (ACL) on each call, activation, or launch of any COM server on the computer. If the access check fails, the call, activation, or launch request will be denied. (This check is in addition to any access check that is run against the server-specific ACLs.) In effect, it provides a minimum authorization standard that must be passed to access any COM server on the computer. The DCOM: Machine Access Restrictions in Security Descriptor Definition Language (SDDL) setting controls access permissions to cover call rights.</p> <p>These computer-wide ACLs provide a way to override weak security settings that are specified by a specific application through CoInitializeSecurity or application-specific security settings. They provide a minimum security standard that must be passed, regardless of the settings of the specific server.</p> <p>These ACLs provide a centralized location for an administrator to set general authorization policy that applies to all COM servers on the computer.</p> <p>The DCOM: Machine Access Restrictions in Security Descriptor Definition Language (SDDL) setting allows you to specify an ACL in two different ways. You can type in the security descriptor in SDDL, or you can choose users and groups and grant or deny them Local Access and Remote Access permissions. Microsoft recommends that you use the built-in user interface to specify the ACL contents that you want to apply with this setting.</p> <p>Vulnerability:</p> <p>Many COM applications include some security-specific code (for example, to call CoInitializeSecurity) but use weak settings that often allow unauthenticated access to the process. Administrators cannot override these settings to force stronger security in earlier versions of Windows without modification of the application. An attacker could attempt to exploit weak security in an individual application by attacking it through COM calls.</p> <p>Also, COM infrastructure includes the RPCSS, a system service that runs during computer startup and always runs after that. This service manages activation of COM objects and the running object table, and provides helper services to DCOM remote. It exposes RPC interfaces that can be called remotely. Because some COM servers allow unauthenticated remote access (as explained in the previous section), these interfaces can be called by anyone, including unauthenticated users. As a result, RPCSS can be attacked by malicious users who use remote, unauthenticated computers.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab DCOM: Machine Access Restrictions in Security Descriptor Definition Language (SDDL) Press Edit Security to see a list of Users that will be allow or denied. Select Check box for the property sheet. <p>Note: If enabled, this may prevent the use of Remote Assistance.(NIST)</p>	Not Defined	Not Defined	Not Defined

Security Options	Multitier Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>DCOM: Machine Launch Restrictions in Security Descriptor Definition Language (SDDL)</p> <p>Security Objective: This policy setting is similar to the DCOM: Machine Access Restrictions in Security Descriptor Definition Language (SDDL) setting in that it allows administrators to define additional computer-wide access controls that govern access to all DCOM-based applications on a computer. However, the ACLs that are specified in <i>this</i> policy setting control local and remote COM <i>launch requests</i> (not access requests) on the computer. The simplest way to think about this access control is as an additional access check call that is done against a computer-wide ACL on each launch of any COM server on the computer. If the access check fails, the call, activation, or launch request will be denied. (This check is in addition to any access check that is run against the server-specific ACLs.) In effect, it provides a minimum authorization standard that must be passed to launch any COM server on the computer. The earlier policy differs in that it provides a minimum access check that is applied to attempts to access an already launched COM server.</p> <p>These computer-wide ACLs provide a way to override weak security settings that are specified by a specific application through CoInitializeSecurity or application-specific security settings. They provide a minimum security standard that must be passed, regardless of the settings of the specific COM server. These ACLs provide a centralized location for an administrator to set general authorization policy that applies to all COM servers on the computer.</p> <p>The DCOM: Machine Launch Restrictions in Security Descriptor Definition Language (SDDL) setting allows you to specify an ACL in two different ways. You can type in the security descriptor in SDDL, or you can choose users and groups and grant or deny them Local Access and Remote Access permissions. Microsoft recommends that you use the built-in user interface to specify the ACL contents that you want to apply with this setting.</p> <p>Vulnerability:</p> <p>Many COM applications include some security-specific code (for example, to call CoInitializeSecurity) but use weak settings that often allow unauthenticated access to the process. Administrators cannot override these settings to force stronger security in earlier versions of Windows without modification of the application. An attacker could attempt to exploit weak security in an individual application by attacking it through COM calls.</p> <p>Also, COM infrastructure includes the RPCSS, a system service that runs during computer startup and always runs after that. This service manages activation of COM objects and the running object table and provides helper services to DCOM remoting. It exposes RPC interfaces that can be called remotely. Because some COM servers allow unauthenticated remote component activation (as explained in the previous section), these interfaces can be called by anyone, including unauthenticated users. As a result, RPCSS can be attacked by malicious users who use remote, unauthenticated computers.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab DCOM: Machine Launch Restrictions in Security Descriptor Definition Language (SDDL) Press Edit Security to see a list of Users that will be allow or denied. Select Check box for the property sheet. Click Okay to complete <p>Note: If enabled, this may prevent the use of Remote Assistance.(NIST)</p>	Not Defined	Not Defined	Not Defined

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Devices: Allow undock without having to log on</p> <p>Security Objective: This policy setting determines whether a user must log on to request permission to remove a portable computer from a docking station. If you enable this policy setting, users will be able to press a docked portable computer's physical eject button to safely undock the computer. If you disable this policy setting, the user must log on to receive permission to undock the computer. Only users who have the Remove Computer from Docking Station privilege can obtain this permission.</p> <p>Note: You should only disable this policy setting for portable computers that cannot be mechanically undocked. Computers that can be mechanically undocked can be physically removed by the user whether or not they use the Windows undocking functionality.</p> <p>The possible values for the Devices: Allow undock without having to log on setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>If this policy setting is enabled, anyone with physical access to portable computers in their docking station could remove them and possibly tamper with them. For computers that do not have docking stations, this policy setting will have no impact.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Devices: Allow undock without having to log policy to set the options. <p>Note:</p> <p>This setting only pertains to controlled undocking, where appropriate services are stopped When the machine is undocked. There is nothing to prevent an attacker from simply ejecting the machine out of the docking station without doing a graceful disconnect.</p> <p>HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System\ undockWithoutLogon = 0</p>	Disabled	Disabled	Disabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p><i>Devices: Allowed to format and eject removable media</i></p> <p><i>Security Objective:</i> This policy setting determines who is allowed to format and eject removable media.</p> <p>The possible values for the Devices: Allowed to format and eject removable media setting are:</p> <ul style="list-style-type: none"> • Administrators • Administrators and Power Users • Administrators and Interactive Users • Not Defined <p><i>Vulnerability:</i></p> <p>Users may be able to move data on removable disks to a different computer where they have administrative privileges. The user could then take ownership of any file, grant themselves full control and view or modify any file. The fact that most removable storage devices will eject media by pressing a mechanical button diminishes the advantage of this policy setting.</p> <p><i>Procedure:</i></p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Devices: Prevent users from installing printer drivers</p> <p>Security Objective: For a computer to print to a network printer, that network printer driver must be installed on the local computer. The Devices: Prevent users from installing printer drivers setting determines who can install a printer driver as part of adding a network printer. If you enable this policy setting, only members of the Administrators and Power Users groups are allowed to install a printer driver when they add a network printer. If you disable this policy setting, any user can install printer drivers when they add a network printer. This policy setting prevents typical users from downloading and installing untrusted printer drivers.</p> <p>Note: This policy setting has no impact if an administrator has configured a trusted path to download drivers. If you use trusted paths, the print subsystem attempts to use the trusted path to download the driver. If the trusted path download succeeds, the driver is installed on behalf of any user. If the trusted path download fails, the driver is not installed and the network printer is not added.</p> <p>The possible values for the Devices: Prevent users from installing printer drivers setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>It may be appropriate in some organizations to allow users to install printer drivers on their own workstations. However, you should not allow users to do so on servers. Printer driver installation on a server may unintentionally cause the computer to become less stable. Only Administrators should have this privilege on servers. A malicious user could install inappropriate printer drivers in a deliberate attempt to damage the computer, or a user might accidentally install malicious code that masquerades as a printer driver.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Devices: Prevent users from installing printer drivers policy to set the options. <p>NOTE:</p> <p>If the printer driver already exists on the local machine, users can add network printers even with this setting enabled.</p> <p>HKLM\System\CurrentControlSet\Control\Print\Providers\LanMan Print Services\Servers\AddPrinterDrivers = 1</p>	Enabled	Enabled	Enabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Devices: Restrict CD-ROM access to locally logged-on user only</p> <p>Security Objective: This policy setting determines whether a CD-ROM is accessible to both local and remote users simultaneously. If you enable this policy setting, only the interactively logged-on user is allowed to access removable CD-ROM media. If this policy setting is enabled and no one is logged on interactively, the CD-ROM can be accessed over the network.</p> <p>The possible values for the Devices: Restrict CD-ROM access to locally logged-on user only setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>A remote user could potentially access a mounted CD-ROM that contains sensitive information. This risk is small, because CD-ROM drives are not automatically made available as network shares; administrators must deliberately choose to share the drive. However, administrators may wish to deny network users the ability to view data or run applications from removable media on the server.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. <p>Domain member: Digitally encrypt or sign secure channel data (always)</p> <p>Security Objective: The following policy settings determine whether a secure channel can be established with a domain controller that cannot sign or encrypt secure channel traffic:</p> <ul style="list-style-type: none"> • Domain member: Digitally encrypt or sign secure channel data (always) • Domain member: Digitally encrypt secure channel data (when possible) • Domain member: Digitally sign secure channel data (when possible) <p>If you enable the Domain member: Digitally encrypt or sign secure channel data (always) setting, a secure channel cannot be established with any domain controller that cannot sign or encrypt all secure channel data.</p> <p>To protect authentication traffic from man-in-the-middle, replay, and other types of network attacks, Windows-based computers create a communication channel through NetLogon called Secure Channels. These channels authenticate computer accounts, and they also authenticate user accounts when a remote user connects to a network resource and the user account exists in a trusted domain. This authentication is called pass-through authentication, and it allows a computer that has joined a domain to have access to the user account database in its domain and in any trusted domains.</p> <p>If you enable the Domain member: Digitally encrypt or sign secure channel data (always) setting, the Domain member: Digitally sign secure channel data (when possible) setting is automatically enabled.</p> <p>The possible values for this policy setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>When a Windows Server 2003, Windows XP, Windows 2000, or Windows NT computer joins a domain, a computer account is created. After it joins the domain, the computer uses the password for that account to create a secure channel with the domain controller for its domain every time that it restarts. Requests that are sent on the secure channel are authenticated—and sensitive information such as passwords are encrypted—but the channel is not integrity-checked, and not all information is encrypted. If a computer is configured to <i>always</i> encrypt or sign secure channel data but the domain controller cannot sign or encrypt any portion of the secure channel data, the computer and domain controller cannot establish a secure channel. If the computer is configured to encrypt or sign secure channel data <i>when possible</i>, a secure channel can be established, but the level of encryption and signing is negotiated.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy->Local Policy</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Domain controller: Refuse machine account password changes policy to set the options. <p>Note: To enable the Domain member: Digitally encrypt or sign secure channel data (always) setting on a member workstation or server, all domain controllers in the domain that the member belongs to must be able to sign or encrypt all secure channel data. This requirement means that all such domain controllers must run Windows NT 4.0 with Service Pack 6a or a later version of the Windows operating system.</p> <p>If this policy is enabled, the policy Domain member: Digitally sign secure channel data (when possible) is automatically enabled.</p> <p>HKLM\System\CurrentControlSet\Services\Netlogon\Parameters\RequireSignOrSeal</p>	Enabled	Enabled	Enabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Domain member: Disable machine account password changes</p> <p>Security Objective: This policy setting determines whether a domain member periodically changes its computer account password. If you enable this policy setting, the domain member cannot change its computer account password. If you disable this policy setting, the domain member is allowed to change its computer account password as specified by the Domain Member: Maximum age for computer account password setting, which is every 30 days by default.</p> <p>Caution: Do not enable this policy setting. Computer account passwords are used to establish secure channel communications between members and domain controllers and, within the domain, between the domain controllers themselves. After such communications are established, the secure channel transmits sensitive information that is needed to make authentication and authorization decisions.</p> <p>Do not use this policy setting in an attempt to support dual-boot scenarios that use the same computer account. If you want to support such a scenario for two installations that are joined to the same domain, use different computer names for the two installations. This policy setting was added to Windows to make it easier for organizations that stockpile pre-built computers that are put into production months later. It eliminates the need for those computers to rejoin the domain. This policy setting is also sometimes used with imaged computers or those with hardware or software level change prevention. Correct imaging procedures make use of this policy unnecessary for imaged computers.</p> <p>The possible values for the Domain member: Disable machine account password changes setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>The default configuration for Windows Server 2003–based computers that belong to a domain is that they are automatically required to change the passwords for their accounts every 30 days. If you disable this policy setting, computers that run Windows Server 2003 will retain the same passwords as their computer accounts. Computers that are no longer able to automatically change their account password are at risk from an attacker who could determine the password for the computer’s domain account.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. <p>Interactive logon: Require smart card (Note: Only enable this setting if a smart card solution is employed)</p> <p>Security Objective: This policy setting requires users to log on to a computer with a smart card.</p> <p>Note: This setting applies to Windows 2000 computers, but it is not available through the Security Configuration Manager tools on these computers.</p> <p>The possible values for the Interactive logon: Require smart card setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>Requirements to use long, complex passwords for authentication enhance network security, especially if the users must change their passwords regularly. This approach reduces the chance that an attacker will be able to guess a user's password by means of a brute force attack. However, it is difficult to make users choose strong passwords, and even strong passwords are vulnerable to brute-force attacks if an attacker has sufficient time and computing resources. The use of smart cards instead of passwords for authentication dramatically increases security, because current technology makes it almost impossible for an attacker to impersonate another user. Smart cards that require personal identification numbers (PINs) provide two-factor authentication. In other words, the user must both possess the smart card and know its PIN. An attacker who captures the authentication traffic between the user's computer and the domain controller will find it extremely difficult to decrypt the traffic and, even if they do, the next time the user logs onto the network a new session key will be generated to encrypt traffic between the user and the domain controller.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Network access: Named Pipes that can be accessed anonymously

Security Objective: This policy setting determines which communication sessions, or pipes, will have attributes and permissions that allow anonymous access.

The possible values for the **Network access: Named Pipes that can be accessed anonymously** setting are:

- A user-defined list of shares
- Not Defined

For this policy setting to take effect, you must also enable the **Network access: Restrict anonymous access to named pipes and shares** setting.

Vulnerability:

You can restrict access over named pipes such as COMNAP and LOCATOR to help prevent unauthorized access to the network. The default list of named pipes and their purpose is provided in the following table.

Table 5.1: Default Named Pipes That Are Accessible Anonymously

Named pipe	Purpose
COMNAP	SNABase named pipe. Systems Network Architecture (SNA) is a collection of network protocols that were originally developed for IBM mainframe computers.
COMNODE	SNA Server named pipe.
SQL\QUERY	Default named pipe for SQL Server.
SPOOLSS	Named pipe for the Print Spooler service.
EPMAPPER	End Point Mapper named pipe.
LOCATOR	Remote Procedure Call Locator service named pipe.
TrkWks	Distributed Link Tracking Client named pipe.
TrkSvr	Distributed Link Tracking Server named pipe.

Procedure: Under Local Security Policy or Default Domain Security Policy->Local Policy

- Double click on the **Security Options policy** object in the right-hand details pane to open the corresponding Security Policy Setting dialog window.
- Select Local Security Setting Tab of **Network access: Named Pipes that can be accessed anonymously** policy to set options. Do not enter any value in the text field

Note: Pipes are internal communication processes that are identified by ID numbers that vary between systems. To facilitate access, pipes are given names that do not vary among systems. This setting determines which pipes will allow anonymous access.

<p>Network access: Sharing and security model for local accounts</p> <p>Security Objective: This policy setting determines how network logons that use local accounts are authenticated. If you configure this policy setting to Classic, network logons that use local account credentials authenticate with those credentials. If you configure this policy setting to Guest only, network logons that use local accounts are automatically mapped to the Guest account. The Classic model provides precise control over access to resources, and allows you to grant different types of access to different users for the same resource. Conversely, the Guest only model treats all users equally as the Guest user account, and they all receive the same level of access to a given resource, which can be either Read Only or Modify.</p> <p>The default configuration in stand-alone Windows XP Professional is Guest only. The default for Windows XP computers that are joined to a domain and Windows Server 2003 computers is Classic. When the computer is not joined to a domain, this policy setting also tailors the Sharing and Security tabs in Windows Explorer to correspond to the sharing and security model that is being used. This setting has no effect on Windows 2000 computers.</p> <p>The possible values for the Network access: Sharing and security model for local accounts setting are:</p> <ul style="list-style-type: none"> • Classic. Local users authenticate as themselves. • Guest only. Local users authenticate as Guest. • Not Defined <p>Vulnerability,</p> <p>With the Guest only model, any user who can authenticate to your computer over the network does so with guest privileges, which probably means that they will not have write access to shared resources on that computer. Although this restriction does increase security, it makes it more difficult for authorized users to access shared resources on those computers because ACLs on those resources must include access control entries (ACEs) for the Guest account. With the Classic model, local accounts should be password protected. Otherwise, if Guest access is enabled, anyone can use those user accounts to access shared system resources.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy->Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Network access: Sharing and security model for local accounts policy to set options. 	Classic-local user authenticate as them selves	Classic-local user authenticate as them selves	Classic-local user authenticate as them selves
<p>Note:</p> <p>This option is set to Classic by default for Windows XP Professional machines joined to a domain. Standalone Windows XP machines set this option to Guest Only by default. Network logons using domain accounts and interactive logons performed by using services such as Telnet or Terminal Services are not affected by this setting.</p> <p>WARNING: The Guest only model allows any user who can access the computer over the network (including anonymous Internet users) the ability to access shared resources.</p> <p>HKLM\System\CurrentControlSet\Control\Lsa\ForceGuest=0</p>

<p>Network security: Do not store LAN Manager hash value on next password change</p> <p>Security Objective: This policy setting determines whether LAN Manager can store hash values for the new password the next time the password is changed.</p> <p>The possible values for the Network security: Do not store LAN Manager hash value on next password change setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability:</p> <p>The SAM file can be targeted by attackers who seek access to username and password hashes. Such attacks use special tools to crack passwords, which can then be used to impersonate users and gain access to resources on your network. These types of attacks will not be prevented if you enable this policy setting, but it will be much more difficult for these types of attacks to succeed.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Network security: Do not store LAN Manager hash value on next password change policy to set options. <p>NOTE: The LAN Manager hash is used for backwards compatibility with pre-Windows NT machines and some applications. Since it is a hash of the Windows password converted to all uppercase and treated as two 7-character passwords, it is easier to crack and is the primary target in password cracking utilities. For this reason, it is recommended that the LM hash not be stored in the SAM. Enabling this option will result in problems with communications to legacy operating systems or applications that only support LANManager authentication.</p> <p>HKLM\System\CurrentControlSet\Control\Lsa\NoLMHash=1</p>	Enabled	Enabled	Enabled

Security Options	Multitier Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Network security: LAN Manager authentication level</p> <p>Security Objective: LAN Manager (LM) is a family of early Microsoft client/server software that allows users to link personal computers together on a single network. Network capabilities include transparent file and print sharing, user security features, and network administration tools. In Active Directory domains, the Kerberos protocol is the default authentication protocol. However, if the Kerberos protocol is not negotiated for some reason, Active Directory will use LM, NTLM, or NTLMv2.</p> <p>LAN Manager authentication includes the LM, NTLM, and NTLM version 2 (NTLMv2) variants, and is the protocol that is used to authenticate all Windows clients when they perform the following operations:</p> <ul style="list-style-type: none"> • Join a domain • Authenticate between Active Directory forests • Authenticate to down-level domains • Authenticate to computers that do not run Windows 2000, Windows Server 2003, or Windows XP) • Authenticate to computers that are not in the domain <p>The possible values for the Network security: LAN Manager authentication level setting are:</p> <ul style="list-style-type: none"> • Send LM & NTLM responses • Send LM & NTLM — use NTLMv2 session security if negotiated • Send NTLM responses only • Send NTLMv2 responses only • Send NTLMv2 responses only\refuse LM • Send NTLMv2 responses only\refuse LM & NTLM • Not Defined <p><i>Continued</i></p>	Send NTLMv2 response only\refuse LM and NTLM	Send NTLMv2 response only\refuse LM and NTLM	Send NTLMv2 response only\refuse LM and NTLM

Security Options

Network security: LAN Manager authentication level

Security Objective: (Continued)

The **Network security: LAN Manager authentication level** setting determines which challenge/response authentication protocol is used for network logons. This choice affects the authentication protocol level that clients use, the session security level that the computers negotiate, and the authentication level that servers accept as follows:

- **Send LM & NTLM responses.** Clients use LM and NTLM authentication and never use NTLMv2 session security. Domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Send LM & NTLM – use NTLMv2 session security if negotiated.** Clients use LM and NTLM authentication and use NTLMv2 session security if the server supports it. Domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Send NTLM response only.** Clients use NTLM authentication only and use NTLMv2 session security if the server supports it. Domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Send NTLMv2 response only.** Clients use NTLMv2 authentication only and use NTLMv2 session security if the server supports it. Domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Send NTLMv2 response only\refuse LM.** Clients use NTLMv2 authentication only and use NTLMv2 session security if the server supports it. Domain controllers refuse LM (accept only NTLM and NTLMv2 authentication).
- **Send NTLMv2 response only\refuse LM & NTLM.** Clients use NTLMv2 authentication only and use NTLMv2 session security if the server supports it. Domain controllers refuse LM and NTLM (accept only NTLMv2 authentication).

These settings correspond to the levels discussed in other Microsoft documents as follows:

- **Level 0 – Send LM and NTLM response; never use NTLMv2 session security.** Clients use LM and NTLM authentication, and never use NTLMv2 session security. Domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Level 1 – Use NTLMv2 session security if negotiated.** Clients use LM and NTLM authentication, and use NTLMv2 session security if the server supports it. Domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Level 2 – Send NTLM response only.** Clients use only NTLM authentication, and use NTLMv2 session security if the server supports it. Domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Level 3 – Send NTLMv2 response only.** Clients use NTLMv2 authentication, and use NTLMv2 session security if the server supports it. Domain controllers accept LM, NTLM, and NTLMv2 authentication.
- **Level 4 – Domain controllers refuse LM responses.** Clients use NTLM authentication, and use NTLMv2 session security if the server supports it. Domain controllers refuse LM authentication, that is, they accept NTLM and NTLMv2.
- **Level 5 – Domain controllers refuse LM and NTLM responses (accept only NTLMv2).** Clients use NTLMv2 authentication, use and NTLMv2 session security if the server supports it. Domain controllers refuse NTLM and LM authentication (they accept only NTLMv2).

<p>Network security: LAN Manager authentication level</p> <p>Vulnerability:</p> <p>Windows 2000, Windows Server 2003, and Windows XP clients are configured by default to send LM and NTLM authentication responses (Windows 9x clients only send LM). The default setting on servers allows all clients to authenticate with servers and use their resources. However, this means that LM responses—the weakest form of authentication response—are sent over the network, and it is potentially possible for attackers to sniff that traffic to more easily reproduce the user's password.</p> <p>The Windows 9x and Windows NT operating systems cannot use the Kerberos version 5 protocol for authentication. For this reason, in a Windows Server 2003 domain, these computers authenticate by default with both the LM and NTLM protocols for network authentication. You can enforce a more secure authentication protocol for Windows 9x and Windows NT by using NTLMv2. For the logon process, NTLMv2 uses a secure channel to protect the authentication process. Even if you use NTLMv2 for legacy clients and servers, Windows-based clients and servers that are members of the domain will use the Kerberos authentication protocol to authenticate with Windows Server 2003 domain controllers.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Network security: LAN Manager authentication level policy to set options. <p>Note:</p> <p>Some Windows processes, such as Cluster Services, use NTLM to authenticate. Use of the recommended setting may cause these services to fail. For more information on NTLM and Cluster Services, see KB Article Q272129 http://support.microsoft.com/default.asp?scid=kb;EN=US;q272129</p> <p>Setting this value higher than 2 on a Windows XP system could prevent some connectivity to systems that support only LM authentication (Windows 95/98, and Windows for Workgroups) or only NTLM (Windows NT 4.0 prior to Service Pack 4). The Active Directory Services client may be installed on Windows 9x machines to allow for NTLMv2 security.</p> <p>HKLM\System\CurrentControlSet\Control\Lsa\LMCompatibilityLevel = 5 (NSA)</p>	Not Defined	Not Defined	Send NTLMv2 response only\refuse LM and NTLM

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Network security: LDAP client signing requirements</p> <p>Security Objective: This policy setting determines the level of data signing that is requested on behalf of clients that issue LDAP BIND requests, as follows:</p> <ul style="list-style-type: none"> • None. The LDAP BIND request is issued with the caller-specified options. • Negotiate signing. If Transport Layer Security/Secure Sockets Layer (TLS/SSL) has not been started, the LDAP BIND request is initiated with the LDAP data signing option set in addition to the caller-specified options. If TLS/SSL has been started, the LDAP BIND request is initiated with the caller-specified options. • Require signature. This level is the same as Negotiate signing. However, if the LDAP server's intermediate saslBindInProgress response does not indicate that LDAP traffic signing is required, the caller is told that the LDAP BIND command request failed. <p>The possible values for the Network security: LDAP client signing requirements setting are:</p> <ul style="list-style-type: none"> • None • Negotiate signing • Require signature • Not Defined <p>Vulnerability</p> <p>Unsigned network traffic is susceptible to man-in-the-middle attacks in which an intruder captures the packets between the client and server, modifies them, and then forwards them to the server. For an LDAP server, this susceptibility means that an attacker could cause a server to make decisions that are based on false or altered data from the LDAP queries. To lower this risk in your network, you can implement strong physical security measures to protect the network infrastructure. Also, you can make all types of man-in-the-middle attacks extremely difficult if you require digital signatures on all network packets by means of IPsec authentication headers.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <ol style="list-style-type: none"> Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Network security: LDAP client signing requirements policy to set options. <p>Note: This policy setting does not have any impact on ldap_simple_bind or ldap_simple_bind_s. No Microsoft LDAP clients that are included with Windows XP Professional use ldap_simple_bind or ldap_simple_bind_s to communicate with a domain controller. <p>Shutdown: Allow system to be shut down without having to log on</p> <p>Security Objective: This policy setting determines whether a computer can be shut down without having to log on to Windows. If you enable this policy setting, the Shut Down command is available on the Windows logon screen. If you disable this policy setting, the Shut Down option is removed from the Windows logon screen. This configuration requires users to be able to log on to the computer successfully and have the Shut down the system user right before they can perform a computer shutdown.</p> <p>The possible values for the Shutdown: Allow system to be shut down without having to log on setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability: Users who can access the console locally could shut down the computer. Attackers could also walk to the local console and restart the server, which would cause a temporary DoS condition. Attackers could also shut down the server and leave all of its applications and services unavailable.</p> <p>Procedure: Under Local Security Policy or Default Domain Security Policy Local Policies Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window. Select Local Security Setting Tab of Shutdown: Allow system to be shut down without having to log policy to set options.</p> <p>Note: HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\System\ShutdownWithoutLogon=0</p>	Disabled	Disabled	Disabled

Security Options	Multiuser Stand Alone (MUSA)	P2P LAN	client/Server AD
<p>Shutdown: Clear virtual memory page file</p> <p>Security Objective: This policy setting determines whether the virtual memory page file is cleared when the computer is shut down. Virtual memory support uses a system page file to swap pages of memory to disk when they are not used. On a running computer, this page file is opened exclusively by the operating system, and it is well protected. However, computers that are configured to allow other operating systems to start might have to make sure that the system page file is wiped clean when the computer shuts down. This confirmation ensures that sensitive information from process memory that might be placed in the page file is not available to an unauthorized user who manages to directly access the page file after shutdown. When you enable this policy setting, the system page file is cleared upon clean shutdown. Also, this policy setting will force the computer to clear the hibernation file Hiberfil.sys when hibernation is disabled on a portable computer. The possible values for the Shutdown: Clear virtual memory page file setting are:</p> <ul style="list-style-type: none"> • Enabled • Disabled • Not Defined <p>Vulnerability</p> <p>Important information that is kept in real memory may be written periodically to the page file to help Windows Server 2003 handle multitasking functions. An attacker who has physical access to a server that has been shut down could view the contents of the paging file. The attacker could move the system volume into a different computer and then analyze the contents of the paging file. Although this process is time consuming, it could expose data that is cached from random access memory (RAM) to the paging file.</p> <p>Caution: An attacker who has physical access to the server could bypass this countermeasure by simply unplugging the server from its power source.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <p>Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window.</p> <p>Select Local Security Setting Tab of Shutdown: Clear virtual memory page file policy to set options.</p> <p>Note: HKLM\System\CurrentControlSet\Control\Session Manager\Memory Management\ClearPageFileAtShutdown=1 (NSA)</p>	Enabled	Enabled	Enabled

This security setting enables or disables certificate rules (a type of software restriction policies rule). With software restriction policies, you can create a certificate rule that will allow or disallow Authenticode®-signed software to run, based on the digital certificate that is associated with the software. For certificate rules to work in software restriction policies, you must enable this security setting.</p> <p>The possible values for the System settings: Use Certificate Rules on Windows Executables for Software Restriction Policies setting are:</p> <p>Enabled Disabled Not Defined</p> <p>Vulnerability</p> <p>Software restriction policies help to protect users and computers because they can prevent the execution of unauthorized code, such as viruses and Trojans horses.</p> <p>Procedure:</p> <p>Under Local Security Policy or Default Domain Security Policy</p> <p>Local Policies</p> <p>Double click on the Security Options policy object in the right-hand details pane to open the corresponding Security Policy Setting dialog window.</p> <p>Select Local Security Setting Tab of System cryptography: Force strong key protection for user keys stored on the computer policy to set options.</p>	Enabled	Enabled	Enabled
<p>Note:</p> <p>In the Windows XP, it is possible to add custom registry settings to the Security Configuration Tool Set. To accomplish this, perform the following actions:</p> <p>Copy the file %SystemRoot%\inf\sceregvl.inf to another file with a different name. This will ensure that a copy of the original exists in case of a problem.</p> <p>Open %SystemRoot%\inf\sceregvl.inf in Notepad, Wordpad, or another text editor</p> <p>Add a line in the form <i>regpath, type, displayname, displaytype</i> where</p> <p><i>regpath</i> – registry key value path, e.g.,MACHINE\System\CurrentControlSet\Control\Lsa\AuditBaseObjects</p> <p><i>type</i> – data type of the registry entry represented by a number. Possible values are REG_SZ (1), REG_EXPAND_SZ (2), REG_BINARY (3), REG_DWORD (4), REG_MULTISZ (7)</p> <p><i>displayname</i> – the name actually displayed in the security template, e.g., “Audit the access of global system objects”</p> <p><i>displaytype</i> – How the interface will display the registry value type. Possible values are Boolean (0), number (1), string (2), choices (3), multivalued (4), bitmask (5). Values 4 and 5 are available on Windows XP only. If choices are specified, the choices should then be specified in the format <i>value1/display1,value2/display2,...</i></p> <p>Re-register scecli.dll by executing regsvr32 scecli.dll at a command prompt</p>			

More Information

The following links provide additional information about security options in Windows Server 2003 and Windows XP.

- For more information about how to restore default security settings in the built-in domain Group Policy objects, see Microsoft Knowledge Base Article "[How to Reset User Rights in the Default Domain Group Policy in Windows Server 2003](http://support.microsoft.com/?scid=324800)" at <http://support.microsoft.com/?scid=324800>.

5. Event Log

The event log records events on the computer, and the Security log records audit events. The event log container of Group Policy is used to define the attributes that are related to the Application, Security, and System event logs, such as maximum log size, access rights for each log, and retention settings and methods. You can configure the event log settings in the following location within the Group Policy Object Editor:

**Computer Configuration\Windows Settings\Security Settings\
Event Log\Settings for Event Logs**

Or Manually configure it via the following procedure:

- Click Start
- 2 - Right-Click "My Computer"
- 3 - Click "Manage"

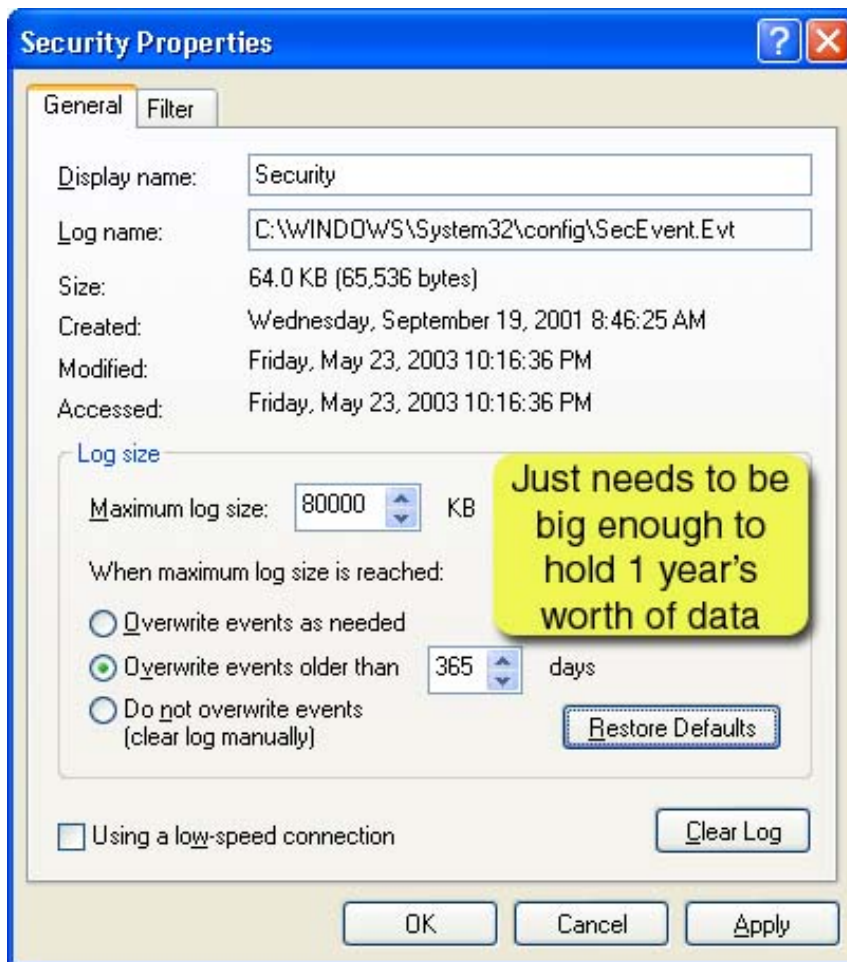

4 - Click the "+" next to Event Viewer.

5 - Right-click Security Log

6 - Click properties.

7 - In the example, the Maximum log size is set at 80,000 KB. Even though we are backing up the file periodically we will use this setting uniformly as a protective measure.

Click OK when finished.

Event Logs Policies	Multituser Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Maximum event log size</p> <p>Security Objective: This policy setting specifies the maximum size of the Application, Security, and System event logs. Although the user interfaces (UIs) of both the Group Policy Object Editor and the Microsoft Management Console (MMC) Event Viewer snap-in allow you to enter values as large as four GB, certain factors make the effective maximum size for these logs much smaller.</p> <p>The Event Log service uses memory-mapped files, and it runs as one of the services under the Services.exe process as Eventlog.dll. When files are loaded in this way, the entire file is loaded into the computer's memory. All of the current versions of Microsoft Windows® have an architectural limitation with regard to memory-mapped files: no process can have more than one GB of memory-mapped files in total. This limitation means that all of the services that run under the Services.exe process must share the one GB pool. The memory is assigned in contiguous 64 KB portions, and if the computer cannot assign additional memory to expand memory-mapped files, problems will occur.</p> <p>For the Event Log service, the use of memory-mapped files means that regardless of the amount of memory that the Maximum event log size setting specifies, log events may no longer be recorded in the log when the computer has no more memory available for the memory-mapped file. Error messages will not be displayed; the events will simply not appear in the event log, or they may overwrite other events that had been recorded previously. Fragmentation of the log files within memory has also been shown to lead to significant performance problems on busy computers.</p> <p>Because of these limitations—even though the theoretical limit for memory-mapped files suggests otherwise and the Event Viewer and Group Policy Object Editor UIs allow you to specify as much as four GB per log—Microsoft has verified that the practical limit is approximately 300 MB on most servers-- that is, 300 MB for <i>all of the event logs combined</i>. On Microsoft Windows XP, member servers, and stand-alone servers, the combined size of the Application, Security, and System event logs should not exceed 300 MB. On domain controllers, the combined size of these three logs plus the Active Directory® directory service, DNS, and Replication logs should not exceed 300 MB.</p> <p>These limitations have caused problems for some Microsoft customers, but the only way to remove the limitations requires fundamental changes to the way system events are recorded. Microsoft is rewriting the event log system to resolve these problems in the next version of Windows.</p>	Security Log =80MB, System Log =80MB, Application Log=80MB	Security Log =80MB, System Log =80MB, Application Log=80MB	Security Log =80MB, System Log =80MB, Application Log=80MB

Event Logs Policies	Multitier Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Maximum event log size (continued)</p> <p>If you significantly increase the number of objects to audit in your organization, there is a risk that the Security log will reach its capacity and force the computer to shut down if you enabled the Audit: Shut down system immediately if unable to log security audits setting. If such a shutdown occurs, the computer will be unusable until an administrator clears the Security log. To prevent such a shutdown, you can disable the Audit: Shut down system immediately if unable to log security audits setting that is described in above section of "Security Options," and increase the Security log size. Alternatively, you can configure automatic log rotation as described in the Microsoft Knowledge Base article "The event log stops logging events before reaching the maximum log size" at http://support.microsoft.com/default.aspx?kbid=312571.</p> <p>Procedure: Event Log → Settings for Event Logs → specific option to view or edit (see detail steps above)</p>			
<p>Prevent local guests group from accessing event logs</p> <p>Security Objective: This policy setting determines whether guests can access the Application, Security, and System event logs.</p> <p>The possible values for the Prevent local guests group from accessing event logs setting are: Enabled Disabled Not Defined</p> <p>Note: This policy setting does not appear in the Local Computer Policy object. This policy setting only affects computers that run Windows 2000 and subsequent versions of Windows.</p> <p>Vulnerability An attacker who has successfully logged onto a computer with guest privileges could learn important information about the computer if they were able to view the event logs. The attacker could then use this information to implement additional exploits.</p> <p>Procedure: Event Log → Settings for Event Logs → specific option to view or edit (see detail steps above) Enable the Prevent local guests group from accessing event logs setting for the policies of all three event logs.</p>	Enabled	Enabled	Enabled

Event Logs Policies	Multitier Stand Alone (MUSA)	P2P LAN	Client/Server AD
<p>Retain event logs</p> <p>Security Objective: This policy setting determines the number of days of event log data to retain for the Application, Security, and System logs if the retention method that is specified for the log is By Days. Configure this setting only if you archive the log at scheduled intervals and you make sure that the maximum log size is large enough to accommodate the interval.</p> <p>The possible values for the Retain event logs setting are:</p> <p>A user-defined number in days between 1 and 365</p> <p>Not Defined</p> <p>Note: This policy setting does not appear in the Local Computer Policy object.</p> <p>A user must be assigned the Manage auditing and security log user right to access the Security log.</p> <p>Vulnerability</p> <p>If you archive the log at scheduled intervals:</p> <p>Open the Properties dialog box for this policy.</p> <p>Specify the appropriate number of days in the Retain application log setting.</p> <p>Select Overwrite events by days for the event log retention method.</p> <p>Also, ensure that the maximum log size is large enough to accommodate the interval.</p>	Enabled	Enabled	Enabled

Event Logs Policies

Retention method for event log

Security Objective: This policy setting determines the wrapping method for the Application, Security, and System logs.

If you do not want to archive the Application log:

Open the **Properties** dialog box for this policy.

Select the **Define this policy setting** check box.

Click **Overwrite events as needed**.

If you want to archive the log at scheduled intervals:

Open the **Properties** dialog box for this policy.

Select the **Define this policy setting** check box.

Click **Overwrite events by days**.

Specify the appropriate number of days in the **Retain application log** setting. Ensure that the maximum log size is large enough to accommodate the interval.

If you must retain all the events in the log:

Open the **Properties** dialog box for this policy.

Select the **Define this policy setting** check box.

Click **Do not overwrite events (clear log manually)**.

This option requires that the log be cleared manually. In this configuration, new events are discarded when the maximum log size is reached.

The possible values for the **Retention method for event log** setting are:

Overwrite events by days

Overwrite events as needed

Do not overwrite events (clear log manually)

Not defined

Note: This policy setting does not appear in the Local Computer Policy object.

Vulnerability

If you significantly increase the number of objects to audit in your organization, there is a risk that the Security log will reach its capacity and force the computer to shut down. If such a shutdown occurs, the computer will be unusable until an administrator clears the Security log. To prevent such a shutdown, you can disable the **Audit: Shut down system immediately if unable to log security audits** setting that is described in Chapter 5, "Security Options" and then increase the Security log size.

If you set the **Event log retention method** to **Manual** or **Overwrite events by days**, it is possible for important recent events to not be recorded or for a DoS attack to occur.

Event Logs Policies

Delegating Access to the Event Logs

In Microsoft Windows Server™ 2003, it is possible to customize the permissions on each event log on a computer. This capability was not available in previous versions of Windows. Some organizations may want to grant read-only access to one or more of the System event logs to some members of the IT team. The access control list (ACL) is stored as a Security Descriptor Definition Language (SDDL) string, in a REG_SZ value called "CustomSD" for each event log in the registry, as in the following example:

HKEY_LOCAL_MACHINE\System\CurrentControlSet
Services\EventLog\CustomSD Create a REG_SZ registry value
O:BAG:SYD:(D;;0xf0007;;;AN)(D;;0xf0007;;;BG)
(A;;0xf0007;;;SY)(A;;0x7;;;BA)(A;;0x5;;;SO)(A;;0x1;;;IU)(A;;0x1;;;SU)
(A;;0x1;;;S-1-5-3)(A;;0x2;;;LS)(A;;0x2;;;NS)

If you edit this value and restart the computer, the new setting will take effect.

Caution: Be careful when you edit the registry values, because there is no "undo" function in the Registry Editor tool. If you make a mistake, you will have to correct it manually. Also, you could accidentally configure the ACLs on an event log in such a way that no one could access it. Be certain that you fully understand SDDL and the default permissions that are placed on each event log before you proceed. Also, be certain to test any changes thoroughly before you implement them in a production environment.

For more information about how to configure security for event logs in Windows Server 2003, see "[How to: Set Event Log Security Locally or by Using Group Policy in Windows Server 2003](http://support.microsoft.com/default.aspx?kbid=323076)" at <http://support.microsoft.com/default.aspx?kbid=323076>.

<p>Note:</p> <p>Saving And Clearing the Audit Logs</p> <p>To save and clear the logs:</p> <p>Select Start → All Programs → Administrative Tools → Event Viewer</p> <ul style="list-style-type: none"> ▪ Click on the log to be cleared in the right pane of the Event Viewer window ▪ Select Clear All Events recommended Action menu ▪ Click Yes to save settings with unique file name ▪ Specify where the log will be saved and then click Save ▪ Click Yes to clear the log ▪ Repeat the above steps for each log <p>Resetting the Audit Log Settings After the System Halts</p> <p>If the system halts as a result of an audit failure, an administrator must restart the system and use the registry editor (regedit.exe) to modify the following registry key value:</p> <p>Hive: HKEY_LOCAL_MACHINE</p> <p>Key: \System\CurrentControlSet\Control\Lsa</p> <p>Name: CrashOnAuditFail</p> <p>Type: REG_DWORD</p> <p>Value: 1</p> <p>NOTE: This value is set by the operating system just before it crashes due to an audit log failure. While the value is 2, only the administrator can log on to the computer. This value confirms the cause of the crash. Reset the value</p>			

More Information

The following links provide additional information about event logging in Windows Server 2003 and Windows XP.

- For more information about how to configure security for event logs in Windows Server 2003, see "[How to: Set Event Log Security Locally or by Using Group Policy in Windows Server 2003](http://support.microsoft.com/default.aspx?kbid=323076)" at <http://support.microsoft.com/default.aspx?kbid=323076>.
- For more information about SDDL, see "[Security Descriptor Definition Language](http://msdn.microsoft.com/library/default.asp?url=/library/en-us/secauthz/security/security_descriptor_definition_language.asp)" on MSDN at http://msdn.microsoft.com/library/default.asp?url=/library/en-us/secauthz/security/security_descriptor_definition_language.asp.

6. Restricted Groups

The Restricted Groups option allows the administrator to manage the membership of sensitive groups. For example, if the Administrators group is to only consist of the built-in Administrator account, the Administrators group can be added to the Restricted Groups option and Administrator can be added in the **Members of Administrators** column. This setting could prevent other users from elevating their privilege to the Administrators group through various attack tools and hacks.

Not all groups need to be added to the Restricted Group list. It is recommended that only sensitive groups be configured through security templates. Any groups not listed will retain their membership lists.

NIST recommends that all users be removed from the Remote Desktop Users group on all systems in all environments, except for those users that specifically need to belong to the group. This will reduce the possibility of someone gaining unauthorized access to the system through Remote Desktop. NIST also recommends restricting membership in the Power Users group because it is nearly equivalent in privileges to the Administrators group. Users should not use an account in the Power Users group to operate a system on a daily basis; such accounts should be treated as Administrators group accounts and used only when necessary. Whenever possible, users who need additional privileges, but not full administrative level access, should be granted the individual privileges needed instead of the range of privileges granted by Power Users group membership. By default, each NIST security template removes all users from the Remote Desktop Users and Power Users groups; the Specialized Security-Limited Functionality template also removes all users from the Backup Operators group. (NIST)

The Restricted Groups option allows the administrator to manage the membership of sensitive groups. This setting could prevent other users from elevating their privilege to the Administrators group through various attack tools and hacks.

Not all groups need to be added to the Restricted Group list. It is recommended that only sensitive groups be configured through security templates. Any groups not listed will retain their membership lists.

The recommended setting in the provided workstation template restricts the Power Users group to having no members. This is generally good security practice. However, environments using older applications or custom written line-of-business applications may require users to have additional privileges similar to the Power Users group on certain files, folders, or registry keys relating to those applications. Ideally, the needed permissions on these files and registry keys should be identified and implemented instead of adding users to the Power Users group. Under no circumstances should you add users to the Administrators group just to make your applications work. (NSA/DISA)

<i>Backup Operators</i> <i>Power Users</i> <i>Remote Desktop Users</i>	None	None	None

7. File System Security

7.1 NTFS

NTFS file system is vastly superior to the other XP file system options—FAT16 and FAT32. Neither FAT16 nor FAT32 provides features for establishing access control for files or encrypting files. The recommendation is to convert to NTFS or use NTFS from the start. Conversion can be achieved with the use of `convert.exe`.

You can also configure the file system security settings at the following location in the Group Policy Object Editor:

Computer Configuration\Windows Settings\Security Settings\File System

7.1.1 Alternative Data Stream (specific for NTFS)

Alternative Data Stream support was added to NTFS (Windows NT, Windows 2000 and Windows XP) to help support Macintosh Hierarchical File System (HFS) which uses stores other information for a file. While this is the intended use (as well as a few Windows internal functions) there are other uses for Alternative Data Streams that should concern security professionals. Using Alternative Data Streams a user can easily hide files that can go undetected unless closely inspection.

Some anti-malware tools understand how to search Alternate Data Streams for malware and they can recognize known spyware in Alternative Data Stream. Other tools are also available to scan the storage devices for hidden files. Most noticeable change would be the changes in the disk storage free space when hidden files have been added. Although the number of files remained constant when listed, the free space would have shown decreased as an indication that hidden files have been introduced.

7.2 Folder Options

Modifying the Folder Options can greatly improve defenses against malware. The system can be configured to show all filenames fully, including their extensions. In addition, Folder Options contains the associations between file types and the default applications that run each file type. By modifying the associations for file extensions that are often used for malicious purposes, such files will be run by the Notepad application, which effectively neutralizes them.

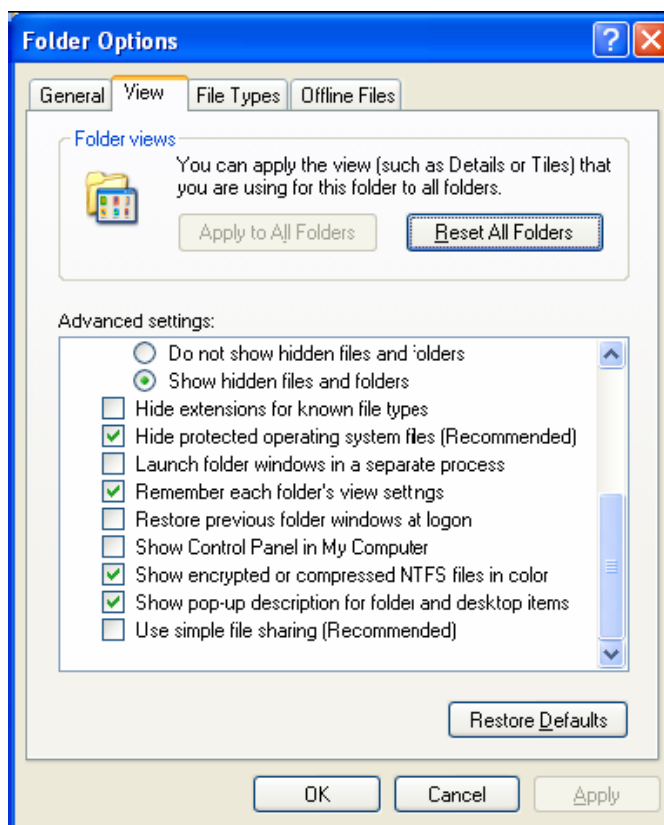

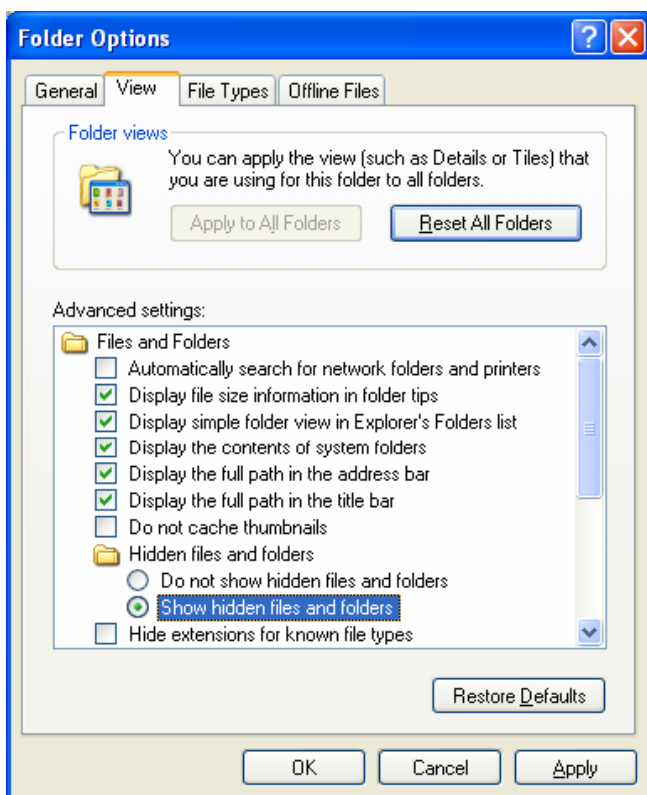

The recommendation is to set Folder options to display all hidden files and extensions. Exclusively, disable the simple file sharing options so that security tab may be accessed.

You can perform the following steps to modify the Folder Options:

1. Click the **Start** menu and choose **Control Panel**.
2. Select **Folder Options**.
3. Verify that the **Show common tasks in folders**, **Open each folder in the same window**, and
4. **Double-click to open an item (single-click to select)** radio buttons are selected.
5. Select the **View** tab. Adjust the settings so that they match the check boxes and radio buttons
6. Select the **File Types** tab. Scroll down the registered file types window to select the **JS** extension
7. and click the **Change** button.

8. Select the **Notepad** program and click **OK**.
9. Repeat the previous two steps to change the mapping for the following extensions: **JSE**, **OTF**, **REG**, **SCT**, **SHB**, **SHS**, **VBE**, **VBS**, **WSC**, **WSF**, and **WSH**.
10. Click the **Close** button and click **OK**.

See Figures below.

7.3 FILE Permission

These are file permissions for files that can typically be found on Windows XP systems. Note that not all of these resources are available on all Windows XP versions and installations. The same file permissions are used for all NIST templates. Additional files are NISPOM files (or security relevant objects)

The NIST security templates restrict access to 32 executables, protecting them from unauthorized modification and usage. Additional custom settings may be added that are specific to the environment in which the Windows XP machine resides. Please note NIST does not offer any additional integrity check such as auditing of these files. However, it is implicit that a Fail access to these objects would be recorded in the security event log. (NIST)

By Defaults, Microsoft security setting provided the file permission for operation systems file security. NISPOM setting of 142 objects are listed below.

Additionally, NISPOM chapter 8 requires file permission to be set for anti-virus software under the program files folders. For some vendors, antivirus installation also involved common shared files. For example c:\Program Files\ Common Files\Symantec Shared. Permissions for these files should be Administrators, System, with full control and users have read and execute permissions. Beside anti-virus installed under program file directory, the back up security log folder should only be accessible by administrators or the auditors.

--	--	--

7.4 Individual File Auditing

Windows XP provides a method to monitor access to any file stored on an NTFS-formatted partition. This auditing method is typically used to monitor access to sensitive files including security relevant files. To configure individual file auditing, perform the following steps:

1. Right-click on the file, and then select **Properties**.
2. Select the **Security** tab and click on **Advanced**.
3. Select the **Auditing** tab and click on **Add** for specify a user or group.
4. As shown in Figure 7-4, select the file permission access attributes that should be audited by clicking in the appropriate **Successful** and **Failed** check boxes.

8. System Services

System services are described differently than the other settings in this guide because the vulnerability, countermeasure, and potential impact statements are almost identical for all services.

8.1 Service Overview

A service must log on to access resources and objects in the operating system, and most services are not designed to have their default logon account changed

Windows Server 2003 includes three built-in local accounts that are used as the logon accounts for various system services:

Local System account. The Local System account is a powerful account that has full access to the computer and acts as the computer on the network. If a service uses the Local System account to log on to a domain controller, that service has access to the entire domain.

Local Service account. The Local Service account is a special, built-in account that is similar to an authenticated user account. It has the same level of access to resources and objects as members of the **Users** group.

Network Service account. The Network Service account is also a special, built-in account that is similar to an authenticated user account. Like the Local Service account, it has the same level of access to resources and objects as members of the **Users** group, which helps safeguard your computer.

You can configure the system services settings in the following location within the Group Policy Object Editor:

**Computer Configuration\Windows Settings\Security Settings\
System Services**

8.2 Vulnerability

Any service or application is a potential point of attack. Therefore, you should disable or remove any unneeded services or executable files in your environment. There are additional optional services available in Windows Server 2003, such as Certificate Services, that are not installed during a default installation of the operating system.

If compromised, services may offer direct access to system resources or fall victim to buffer overflows or denial of service attacks. Therefore, the proper configuration of services is an important security step. Since services are environment and application specific, no services are configured specifically under NSA/DISA or NISPOM. However, there are a few guidelines to consider when configuring services:

Only run necessary services. For example, if the telnet service or FTP service is running on a system, but not being used, disable it.

Ensure that only a limited number of users/groups can start, stop, or change a service.

If a service is listed, but not needed, change the startup mode to Disabled instead of Manual. This will ensure that the service cannot be restarted by an unauthorized or malicious user. Also, if a service is currently disabled and will remain that way, it is recommended that it be explicitly set to Disabled versus “Not defined.”

When configuring either the startup mode or access control list for a service, you must configure the other as well. When a service is explicitly disabled, its ACL should also be secured by changing the default ACL from Everyone Full Control to grant Administrators and SYSTEM Full Control and Authenticated Users Read access.

Run services with the least privilege necessary. For example, do not run a service as a domain administrator if user privileges are sufficient.

8.3 Service Settings

System Services	Setting
Alerter	Disabled
Application Layer Gateway Service	Not Defined
Application Management	Not Defined
Automatic Updates	Disabled
Background Intelligent Transfer Service	Not Defined
ClipBook	Not Defined
COM+ Event System	Not Defined
COM+ System Application	Not Defined
Computer Browser	Not Defined
Cryptographic Services	Not Defined

Windows Management Instrumentation Driver Extensions	Not Defined
Windows Time	Not Defined
Wireless Zero	Disabled

Configuration	Not Defined
WMI Performance	Not Defined
Adapter Not defined	Not Defined
Workstation	Not Defined
World Wide Web Publishing Services	Disabled

8.4 Remote Access

The procedure for disabling the Remote Assistance and Remote Desktop features is different than disabling other services. Although these features are helpful for support, they also expose the computer to network-based attacks. As such, unless an organizational requirement exists to have them enabled, perform the following steps to disable them:

1. Right-click **My Computer** and select **Properties**.
2. Select the **Remote** tab and uncheck the **Allow Remote Assistance invitations to be sent from this computer** and **Allow users to connect remotely to this computer** boxes. Click **OK**.

9. Registry Keys

In order to implement adequate security in a Windows XP/2003 server environment, some registry key permissions should be changed. By default, permission to manipulate the registry is restricted, but because of the value of the registry, it is important to verify that the registry is protected. Following list is a recommended registry setting for security configuration. Permission on registry keys is set by default to Administrators full control, System Full Control, User Read.

Note: NSA/DISA set registry key permission but did not provide value for the keys.

Registry Keys	Setting
HKKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurePipeServers\winreg. Setting access permission to the registry	Administrator has Full Control, Backup Operators group has special permissions Query Value, Enumerate Subkeys, Notify, and Read Control, and LOCAL SERVICE has Read permissions
HKLM\Software\Microsoft\DrWatson\CreateCrashDump	0

Setting this value to 0 disables the creation of a memory dump file by the Dr. Watson program debugger. ⁹⁸ Memory dumps can contain sensitive information such as passwords. See Section 7.9 for additional information on suppressing memory dump file creation. This setting should be enabled to troubleshoot a recurring problem	
HKLM\Software\Microsoft\Windows NT\CurrentVersion\AEDebug\Auto Setting this value to 0 disables Dr. Watson.	0
HKLM\System\CurrentControlSet\Services\CDrom\Autorun Setting this value to 0 disables the autorun feature for CDs	0
HKLM\System\CurrentControlSet\Services\MrxSmb\Parameters\RefuseReset Setting this parameter to 1 causes the system to ignore ResetBrowser frames. Such frames can be used to shut down NetBIOS and master browsers and to declare a computer as being the new master browser. Earlier versions of Windows could be attacked through ResetBrowser frames.	1
HKLM\System\CurrentControlSet\Services\TCPIP\Parameters\EnablePMTUDiscovery When this parameter is set to 1, TCP attempts to discover the Maximum Transmission Unit (MTU), the size of the largest packet that can be kept intact over the path to a remote host. Setting this parameter to 0 disables the feature and causes an MTU of 576 bytes to be used for all connections that are not made to hosts on the local subnet.	Not defined

HKLM\System\CurrentControlSet \Services\TCPIP\Parameters \PerformRouterDiscovery This parameter controls whether the system attempts to perform router discovery per RFC 1256 on a per-interface basis. This feature should be disabled by setting the value to 0.	0
HKLM\System\CurrentControlSet \Services\TCPIP\Parameters \TcpMaxHalfOpen This setting specifies the number of connections permitted in the SYN-RCVD state before SynAttackProtect measures are implemented.	100
HKLM\System\CurrentControlSet \Services\TCPIP\Parameters \TcpMaxHalfOpenRetried This setting specifies the number of connections permitted in the SYN-RCVD state for which at least one retransmission of the SYN has been sent, before SynAttackProtect measures are implemented.	80
HKLM\System\CurrentControlSet \Services\TCPIP\Parameters \TCPMaxPortsExhausted This setting specifies how many connection requests can be refused before SynAttackProtect measures are implemented.	5
HKLM\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\ScreenSaverGracePeriod. This value sets the grace period between the activation of a password-protected screen saver and the requirement to enter a password to unlock the system. Setting this value to 0 eliminates the grace period.	0
HKLM\System\CurrentControlSet\Control\FileSystem\NtfsDisable8dot3NameCreation. Setting this value to 1 disables the automatic creation of legacy filenames in 8.3 format.	1

HKLM\System\CurrentControlSet\Control\Session Manager\SafeDllSearchMode. Windows XP searches directories in a particular order when it is looking for a file to execute. By default, Windows searches the current directory before the Windows and system directories. Setting this parameter to 1 causes Windows to search the Windows and system directories before searching the current directory. This is a better security practice because the current directory may be less restrictive than the Windows and system directories.	1
HKLM\System\CurrentControlSet\Services\EventLog\Security\WarningLevel. This value corresponds to a percentage of the maximum size of the security event log. When the security event log's size reaches the specified percentage, the system issues a warning.	80
HKLM\System\CurrentControlSet\Services\RasMan\Parameters\DisableSavePassword. Setting this parameter to 1 prevents the Network Connections phone book from saving passwords used for remote access.	1
HKLM\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\NoDriveTypeAutoRun. ⁹⁴ The autorun feature attempts to run content from a CD automatically when it is placed in the system. If a CD contains malicious content, it could be automatically run. Setting this registry value to 255 disables the autorun feature for all types of drives.	255
HKLM\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\AutoAdminLogon. If enabled, this registry value allows the system login to be bypassed by using a password stored in cleartext within the registry. This password may be viewable by local users of the system. Also, an unauthorized party who gains physical access to the system may be able to gain access without providing any authentication. Setting the registry value to 0 disables the feature.	0
HKLM\System\CurrentControlSet\Control\CrashControl\AutoReboot. Enabling the AutoReboot feature causes the system to restart automatically after a failure or lockup. Some consider this to be undesirable from a security and operational standpoint.	0

10. Network Communication Ports

Windows XP/2003 Systems utilize network communication ports and systems services to provide wide variety of systems and network functions. As described in System services of this document, the recommended security configuration is to minimize the number of open ports and system services. Following table list a set of Windows system commonly used network ports.

10.1 Common Ports and Services

Port	Protocol	Service	Description
21	TCP	FTP	File
23	TCP	Telnet	Telnet service
68	UDP	DHCP	Dynamic Host Configuration Protocol client
80	TCP	HTTP	HyperText Transfer Protocol server
123	UDP	NTP	Network Time Protocol client (Windows Time)
135	TCP	epmap	DCE Endpoint Resolution (remote procedure call)
137	UDP	NetBIOS-ns	NetBIOS Name Service
138	UDP	NetBIOS-dgm	NetBIOS Datagram Service
139	TCP	NetBIOS-ssn	NetBIOS Session Service
161	UDP	SNMP	Simple Network Management Protocol
213	UDP	IPX	Over IP Client Service for Netware service
443	TCP	HTTPS	HTTP over SSL server
389	TCP/UDP	LDAP	Active Directory
445	TCP	UDP	microsoft-ds (SMB) Microsoft Common Internet File System (CIFS)
500	UDP	IKE	Internet Key Exchange (often used with IPsec)
515	TCP	LPR	Print Spooler service
522	TCP	NetMeeting	client178
636	TCP/UDP	LDAP SSL	Secure Channel for LDAP
1503	TCP	NetMeeting	client
1701	UDP	L2TP	Layer 2 Tunneling Protocol client
1720	TCP	NetMeeting	client
1723	TCP/UDP	PPTP	Point-to-Point Tunneling Protocol client
1731	TCP	NetMeeting	client
1900	UDP	SSDP	Simple Service Discovery Protocol
-2001			
2120			
UDP	Windows	Messenger	voice calls179
2869	TCP	UPnP	Universal Plug and Play
3002	TCP	Windows	Firewall/Sharing
3003	TCP	Windows	Firewall/Sharing
3389	TCP	RDP	Remote Desktop Protocol service
4500	UDP	L2TP/IPsec	NAT-T L2TP/IPSec
5000	TCP	UPnP	Universal Plug and Play
6801	UDP	Windows	voice calls

		Messenger	
-6891		Windows	
6900	TCP	Messenger	file transfers
		Windows	
6901	TCP/UDP	Messenger	voice calls

10.2 Stand Alone System

For standalone systems, the recommendation is to turn off the network interface from the operating system or from the bios of the PC.

10.3 Windows Firewall

For most applications, the Windows Firewall component provides adequate host-level protection against malicious inbound traffic. The Security Configuration Wizard (SCW) in Windows Server 2003 with SP1 greatly simplifies the setup and management of Windows Firewall settings for large deployments. IPsec should be used to secure host-to-host and host-client traffic where appropriate, and Windows Firewall should typically be widely deployed within most organizations as an additional defensive layer.

Note: There is no NISPOM requirement to set Window firewall. This firewall does not meet the CCVD EAL level required as a control interface.

10.4 Banner between network services

The recommendation for interactive connection between services of different machines should provide a banner to indicate the machine and the legal responsibilities. However, Some application services may not have the capabilities. However, Windows FTP and Telnet properties includes the ability to have Banner (see FTP site welcome property) displayed before login.

10.5 Disabling USB storage devices

The ability to use tiny USB memory sticks to download and walk away with relatively large amounts of data has already made the ubiquitous devices a potent security threat in the computing environment. Now, the emergence of USB flash drives that can store and automatically run applications straight off the device poses even more threat. The recommendation is to disable the USB storage device. This section describe two methods that can be used to prevent users from connecting to a USB storage device.

10.5.1 USB Storage Device Is Not Already Installed on the Computer

If a USB storage device is not already installed on the computer, assign the user or the group Deny permissions to the following files:

%SystemRoot%\Inf\Usbstor.pnf

%SystemRoot%\Inf\Usbstor.inf

When you do so, users cannot install a USB storage device on the computer. To assign a user or group Deny permissions to the Usbstor.pnf and Usbstor.inf files, follow these steps:

Start Windows Explorer, and then locate the %SystemRoot%\Inf folder

1. Right-click the **Usbstor.pnf** file, and then click **Properties**
2. Click the **Security** tab
3. In the **Group or user names** list, click the user or group that you want to set Deny permissions for.
4. In the **Permissions for *UserName or GroupName*** list, click to select the **Deny** check box next to **Full Control**, and then click **OK**.
Note In addition, add the System account to the **Deny** list.
5. Right-click the **Usbstor.inf** file, and then click **Properties**.
6. Click the **Security** tab
7. In the **Group or user names** list, click the user or group that you want to set Deny permissions for.
8. In the **Permissions for *UserName or GroupName*** list, click to select the **Deny** check box next to **Full Control**, and then click **OK**

10.5.2 USB Storage Device Is Already Installed on the Computer

Warning Serious problems might occur if you modify the registry incorrectly by using Registry Editor or by using another method. These problems might require that you reinstall your operating system.

If a USB storage device is already installed on the computer, set the **Start** value in the following registry key to 4:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\UsbStor

When you do so, the USB storage device does not work when the user connects the device to the computer. To set the **Start** value, follow these steps:

1. Click **Start**, and then click **Run**
2. In the **Open** box, type **regedit**, and then click **OK**
3. Locate, and then click the following registry key:
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\UsbStor
4. In the right pane, double-click **Start**
5. In the **Value data** box, type **4**, click **Hexadecimal** (if it is not already selected), and then click **OK**.
6. Quit Registry Editor

10.5.3 USB Storage and System Events

When a USB storage device has been mounted, the system log will have an entry indicating the type of devices have been loaded. The event flags are Event ID 134/135/160 in the system event log, indicating USB storage device activity. The USB storage also creates a registry entry. See Registry entry in \CurrentControlSet\Enum\USBSTOR. These events require monitoring/auditing in meeting the NISPOM requirement for media controls and configuration management.

10.6 Disabling IPv6 protocol

IPv6 have mandated IPsec in its transport protocol, the compatibility issues usually forces the IPv6 being deployed without cryptography. The addition of IPsec in IPv6 does not affect the application layer. IPv6 ability to have multiple tunneling mechanisms allows unauthorized traffic to transit without knowing the source address. IPv6 benefits may out weight the security risk for implementing the protocol in some cases. The recommendation is to disable or uninstall IPv6 if not needed. Please note, some networking systems may require implementation of IPv6, such as firewall. In these implementations, the recommendation would be to include strong cryptography and filtering (such as RFC 2827 filtering) to avoid layer 4 spoofing.

IPv6 protocol for Windows XP with SP1 or later or Windows Server 2003 can be disabled by doing the following:

1. Log on to the computer with a user account that has privileges to change network configuration.
2. Click **Start**, click **Control Panel**, and then double-click **Network Connections**.
3. Right-click any local area connection, and then click **Properties**.
4. Click **Microsoft TCP/IP version 6** (for Windows XP with SP2 or later or Windows Server 2003) or **Microsoft IPv6 Developer Edition** (for Windows XP with SP1), and then click **Uninstall**.
5. When prompted to confirm the removal of the Microsoft IPv6 Developer Edition or Microsoft TCP/IP version 6 protocol, click **OK**.

Alternately, from the Windows XP or Windows Server 2003 desktop, click **Start**, point to **Programs**, point to **Accessories**, and then click **Command Prompt**. At the command prompt, type **netsh interface ipv6 uninstall**.

To remove the IPv6 protocol for Windows XP with no service packs installed, do the following:

Log on to the computer with a user account that has local administrator privileges.

From the Windows XP desktop, click **Start**, point to **Programs**, point to **Accessories**, and then click **Command Prompt**

At the command prompt, type **ipv6 uninstall**.

Alternately, from the Windows XP or Windows Server 2003 desktop, click **Start**, point to **Programs**, point to **Accessories**, and then click **Command Prompt**. At the command prompt, type **netsh interface ipv6 uninstall**.

To remove the IPv6 protocol for Windows XP with no service packs installed, do the following:

Add the following registry value (DWORD type) set to 0xFF:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip6\Parameters\DisabledComponents

This method disables IPv6 on all your LAN interfaces, connections, and tunnel interfaces but does not disable the IPv6 loopback interface.

11. Conclusion

This document contains significant security settings that are available in Microsoft Windows Server 2003 with SP1 and Microsoft Windows XP Professional with SP2.

This document provided a summary of baseline technical security configuration standards for Windows 2000/XP/2003 systems. The document does not provide a complete step by step guide on how to set up the security. However, the implementation procedures for each component are described and provide a road map to the basic security configurations.
